March 4, 1976

Mr. Sam F. Cryderman, Deputy Director
Bureau of Transportation Planning
Michigan Department of State Highways
and Transportation
State Highways Building
Post Office Drawer K
Lansing, Michigan 48904

Dear Mr. Cryderman:

The accompanying report, Economic and Travel Impacts of Speed Limit Reduction Using a Statewide Transportation Modeling System, was first brought out in September of 1974 as an in-house working paper. Because the subject of speed reduction impacts has received increasing attention in recent transportation literature, we feel that this would be a proper time to make this report public.

The report documents a process now being used in the Statewide Transportation Modeling System to predict three impacts of speed limit reduction which were previously difficult to address at the system level; the additional driving times necessitated by slower speeds, the value of the time lost, and a comparison of the probable number of trips made before and after speed limit reduction. Such calculations are particularly valuable in gauging the possible effects of a speed reduction before it is actually implemented.

Because this document has been published after the present 55 mile-per-hour speed limit was an accomplished fact, it should not be construed as a criticism of that decision. Moreover, any such judgment would be hasty because the report treats only a few of the issues which can be investigated when a deceleration program is proposed. We only hope that this is a demonstration of the manner in which statewide transportation modeling results could be used in formulating policy decisions.

Sincerely,

R. J. Lilly, Administrator
Highway Planning Division

PREFACE

STATE WIDE

PREFACE

The statewide transportation modeling system has been applied in analysis of the impact of the 50 mph speed limit issue created as the result of the gasoline shortage during the fall of 1973 and the spring of 1974. The probable impact of this speed alteration, generated by a computerized statewide model, is documented in this report. Example and illustrations from the output of this model are included.

The accuracy and reliability of the results are indicated by these sample computer runs. The applicability of this method in the decision making process can be determined from this report. These travel impacts could be used, within the limits determined above, as a basis for administrative or legislative action.

This report has been completed "after the fact" as most energy crisis issues regarding speed limit change have been settled, but this document may still serve as a basis for future statewide transportation modeling applications.

INTRODUCTION

STATEWIDE

INTRODUCTION

The statewide highway network, shown in Figure 1, was used to generate the speed limit reduction travel impacts. This network consists of all state trunklines and selected county roads. Links--segments of these roads--are catalogued according to pairs of link node numbers. Nodes are reference points at each end of a link which define the link. The locations of nodes and a series of links are shown in Figure 2. Each of these sections has associated with it a set of parameters which describes the physical conditions of the link. These variables are listed in Figure 3.

The link-node technique is being used to store and access both physical and travel conditions of the actual road sections. This data is stored on magnetic tape. Corresponding parameters for all links are found in the same location or volume fields on the tape.

The computer programs in the Michigan transportation analysis battery are capable of reading up to fifty specific volume fields for each link in the network. This allows the user to complete many different types of analysis using the same network file. A test to select all links with a specific value of a given field can also be performed. Mathematical manipulation of any volume field can be performed on selected links, or the whole network.

The trip generation and travel time calculations are two computer operations based on network files. Time calculation is dependent on the link speed and the total distance on the shortest time path between two zone pairs. Michigan's zone system appears

in Figure 4 and is composed of 508 instate zones and 39 outstate zones. Variations in speed made over the whole network or only on selected links could have a striking effect on travel times between may zone pairs. The impact of these alterations will be discussed in the system impact analysis section. The speed limit change impacts affect driving time and also have a definite effect on trip generation. Driving time impacts can also be converted to dollar values as a possible measure of economic impact. The statewide transportation modeling system will be used to measure these impacts.

The next section of this document deals with a detailed explanation of the actual procedure followed and the computer programs used in this analysis tests of deiving time and trip generation impacts are stepped through. The final sections are an explanation of the actual tests of the probable speed limit reduction impacts on the State of Michigan.

(FIGURE 4 CONTINUED)

IMPACT ANALYSIS PROCEDURES

IMPACT ANALYSIS PROCEDURES

The task stated in the preface, measurement of the impacts caused by a speed reduction, was started with the plotting of the network shown in Figure 1. A flow chart of the other steps taken during this procedure is shown in Figure 5. Our highway network plotting program allowed us to print the velocity of each link. This initial plot contained speeds as high as the 62 mph avg. speed used on most rural freeways.

The network plotted in the previous step was then manipulated by a Cobol program. The program used in this network manipulation altered speed to conform with a 50 mph speed limit. All speeds on the original network that were originally greater than 50 were reduced to 50 mph. Once processed the network was ready to be ran with the programs of the transportation planning battery.

This altered network and the original net were input to the programs that create and plot trees. These program selected the shortest time routes and plotted them from specified zones. An example of the output of this process shown in Figure 6. This plotting was done after the differences between the two speeds were calculated.

Skim trees of time were then generated and printed. The tapes put out by these skim tree programs, for both the old and new networks, were manipulated by other programs of the transportation planning battery. This second processing gave the differences between the two time skims, which represent the additional driving times necessitated by reduced speeds.

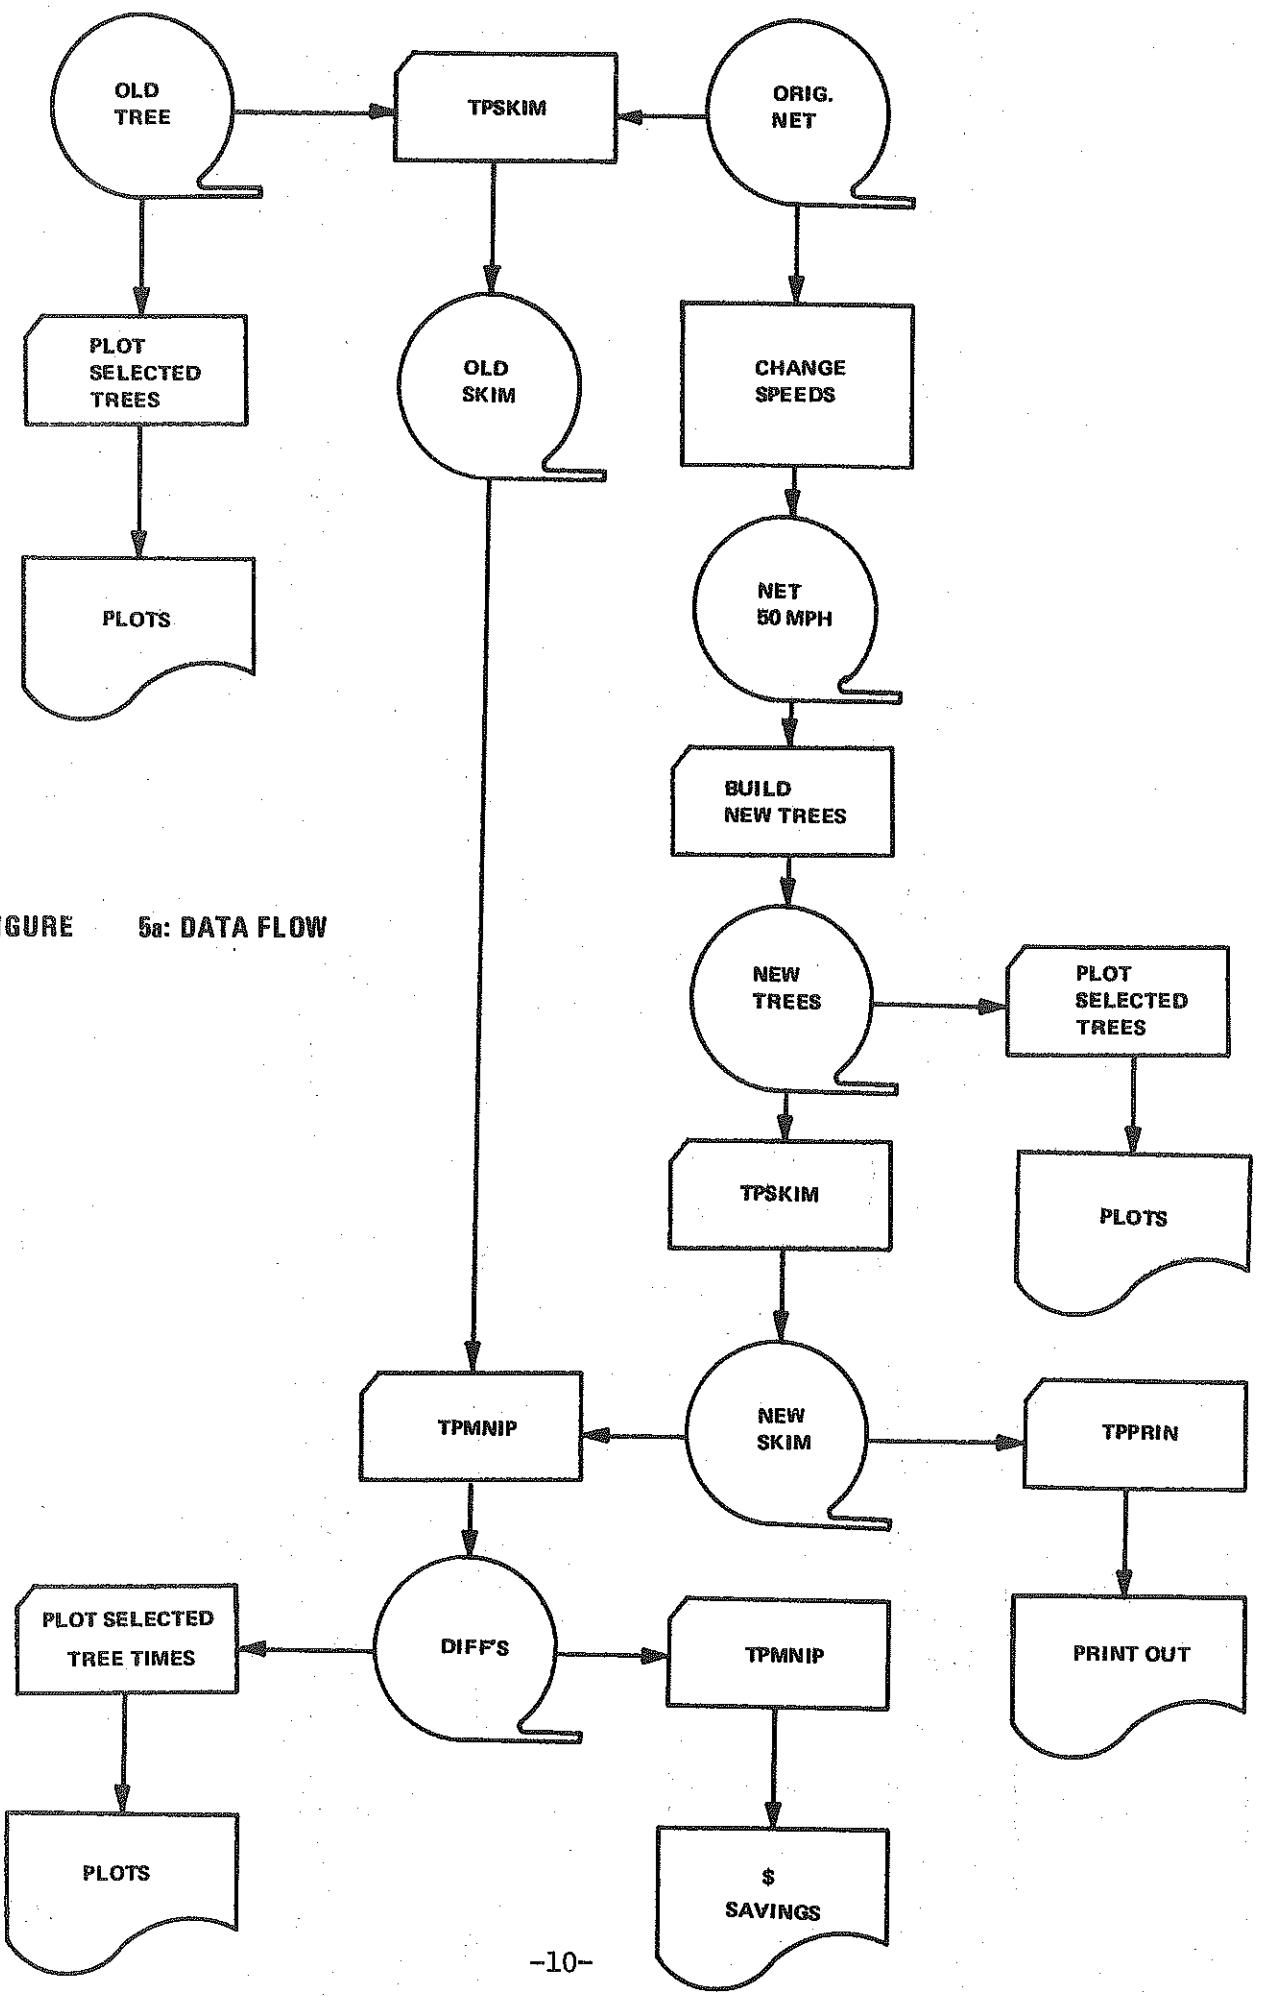

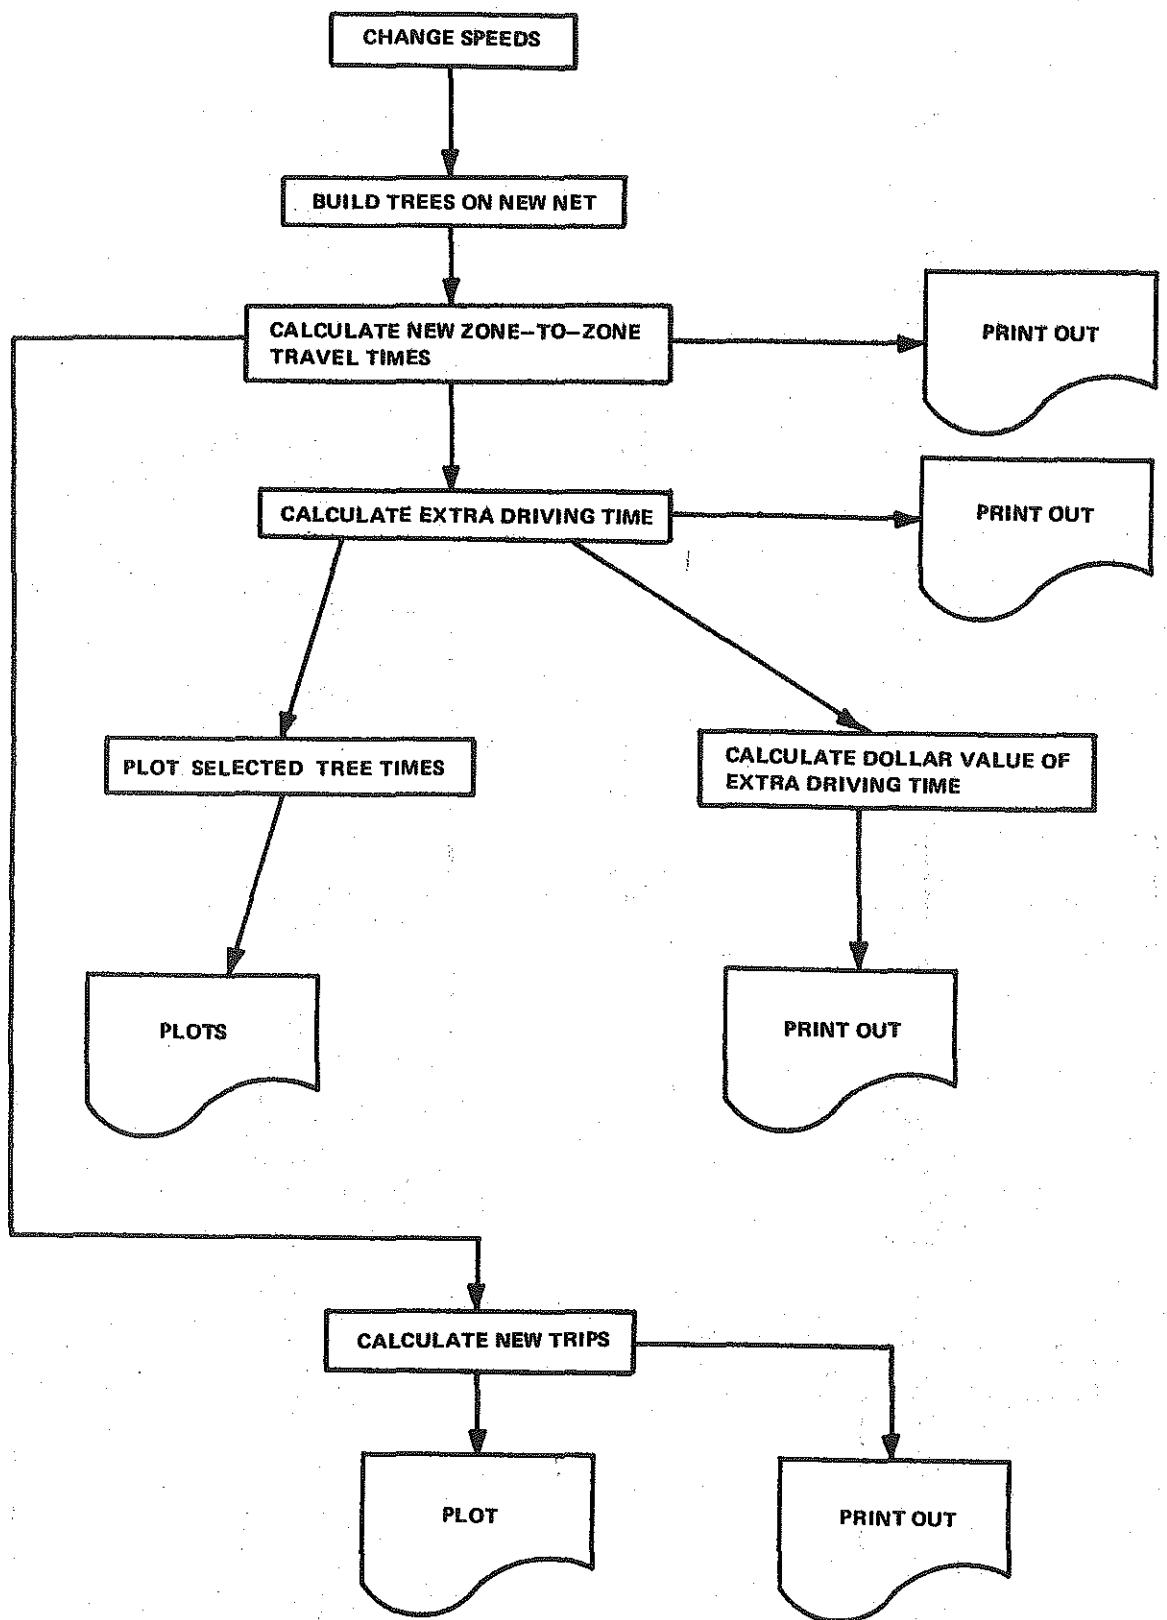

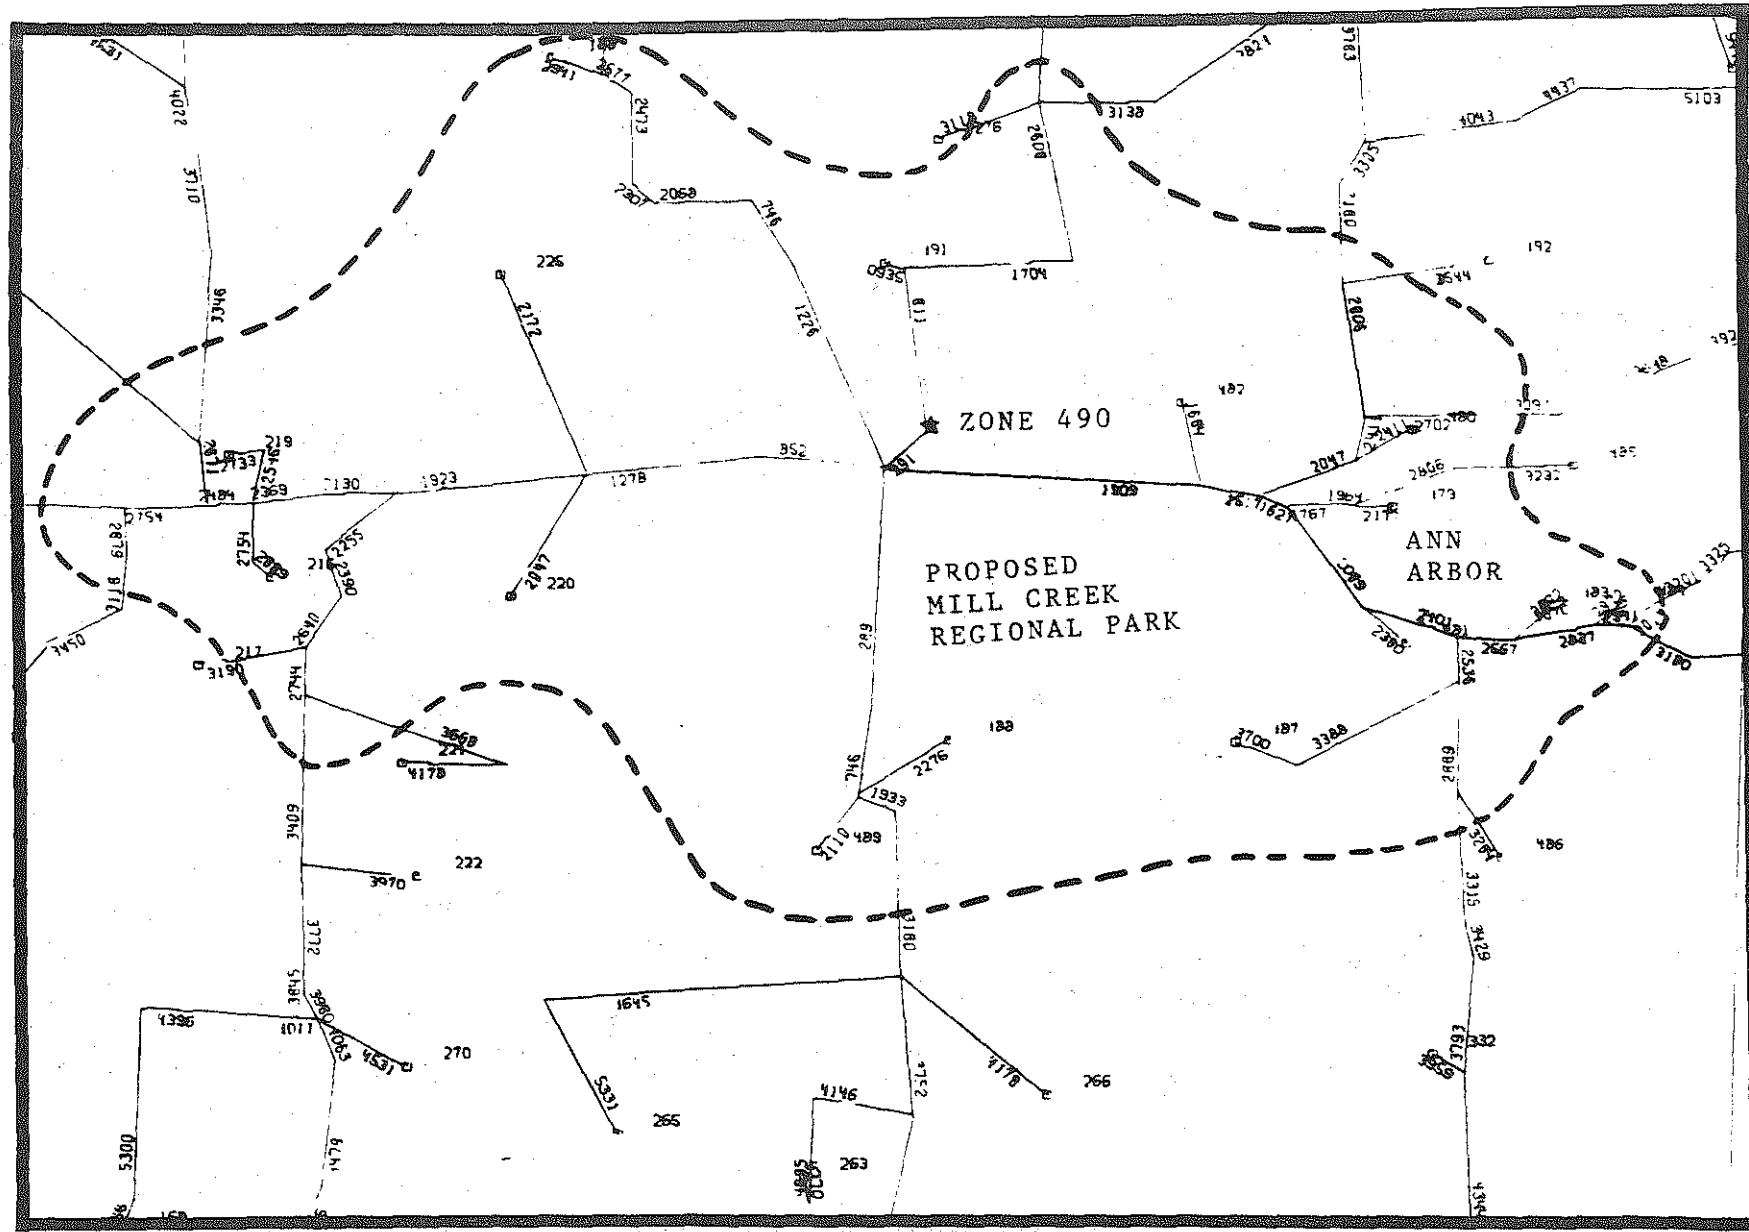

FIGURE 5a: DATA FLOW

FIGURE 5b: ANALYSIS PROCEDURE

-12-

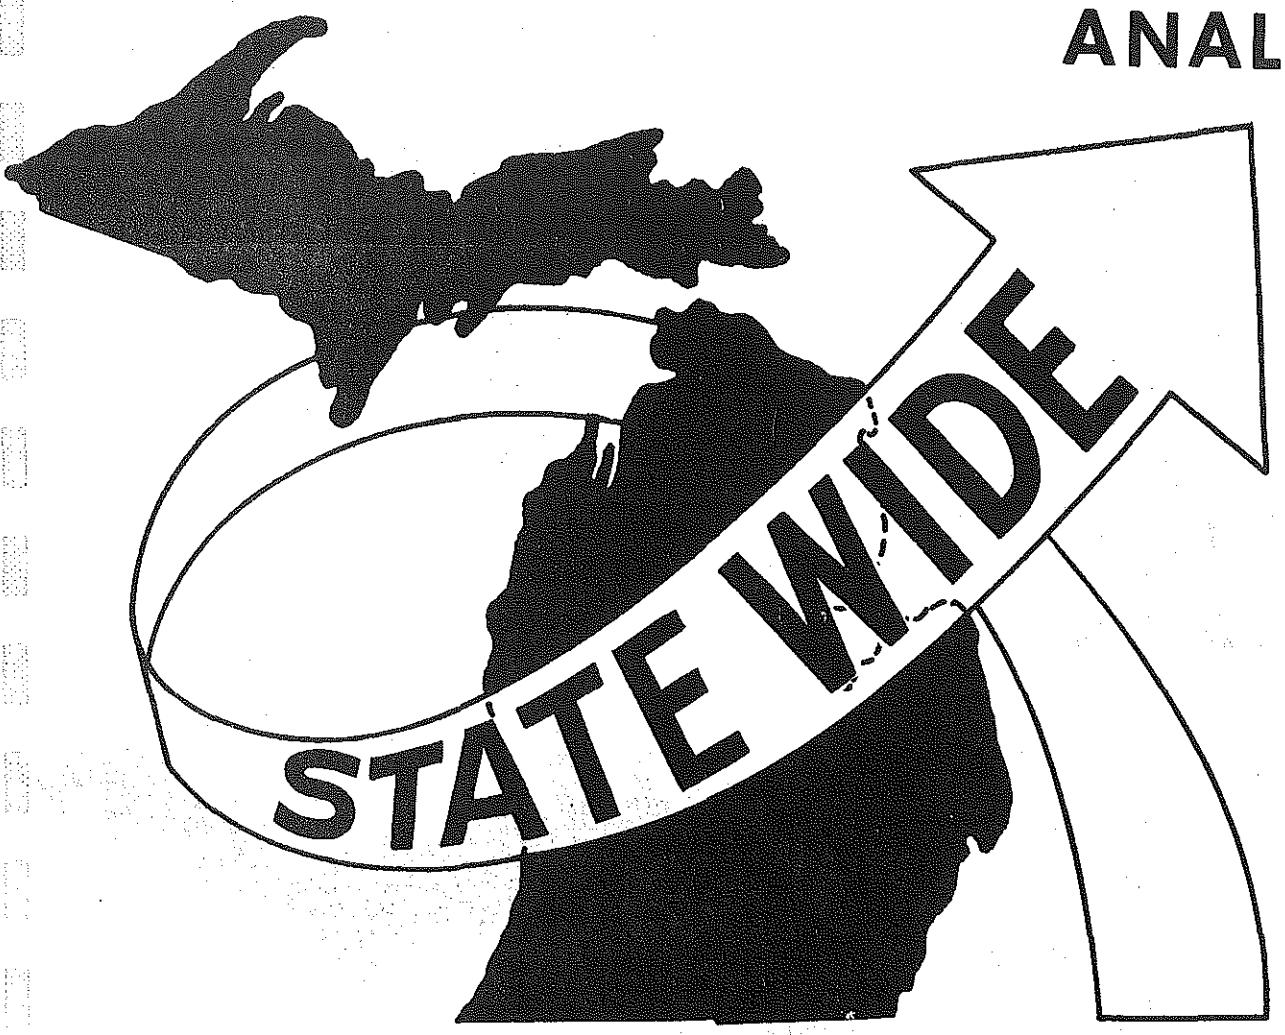

Another program of the transportation planning battery, the trip generator, was also run during this analysis. The output, a printed computer listing, gave the number of trips generated by the network under existing conditions. Manipulation of the two matrices also gave the differences in the number of trips. This value of time was derived by inflating the value cited by SRI for auto VDT for auto VOT, \$2/hr. by using cost trends from Summary of National Travel Statistics, DOT, 1971.

Using the \$2.52/hr as the value of time and the two matrices, discussed in preceding paragraphs, another matrix was produced. This table gave the economic changes resulting from the speed reduction.

Additional analysis of these two networks before and after speed reduction, was performed. A ratio of the number of trips generated by each was calculated. This was plotted on the state highway network.

SYSTEM IMPACT ANALYSIS

SYSTEM IMPACT ANALYSIS

In analyzing the effects of the lowered speed limit three basic types of results should be examined:

- (1) additional driving time necessitated by slower speeds
- (2) value of time lost

and (3) a comparison of the number of trips which would probably be made at a maximum speed of 50 miles per hour with those which would be made under "normal" conditions

The amount of additional driving time required to go from one place to another is expressed in "trip-minutes", defined by the formula:

$$\left(\begin{array}{l} \text{trip-minutes} \\ \text{between zones } i \text{ and } j \end{array} \right) = \left(\begin{array}{l} \text{avg. driving time/trip} \\ \text{between } i \text{ and } j \end{array} \right) \times \left(\begin{array}{l} \text{no. of trips} \\ \text{between } i \text{ and } j \end{array} \right)$$

It is useful to examine the time lost in driving between selected origin-destination points, as is done in Figure 7. Also, one may be interested in the total trip-minutes lost by the residents of a particular area or region, regardless of their ultimate destination. An example of this sort of result is shown by Figure 8. The extra time spent driving can also be shown on the links of a "selected tree", or the highway paths from a selected zone to all other zones. A portion of such a plot is shown in Figure 9.

Moreover, this extra time spent driving can be costed, using a dollar value for each trip-minute lost or gained. This value is not what a person might earn during that minute, but what he might pay to save a minute's driving time which he could be using for something

FIGURE 9: EXTRA DRIVING TIMES

else. At a rate of \$2.52 per hour per trip, Figures 10 and 11 show the value of the extra driving times given in Figures 7 and 8. The above tables are shown for all zones in Appendix A.

The final result is possibly the most interesting. It is well-known that if a given trip is made to take longer, some people will simply refuse to go, or refuse to go as often. This deals with the whole notion of "induced" travel, that as two places become relatively more accessible to one another, the travel between them increases. This has another, even more complicated, sidelight: if a city which is the main travel attractor for a region is suddenly made less accessible relative to neighboring cities, some of the travel which had gone to the city previously will go to its neighbors. This could happen, for example, if one city in a county lay on the crossroads of two freeways, and other cities of comparable size lay on slower two-lane roads; if the speed limit on the expressways were suddenly dropped, that first city's share of the trips in the county would be diminished. Figure 12 presents a table comparing the number of forecasted trips into and out of certain areas before and after a speed limit reduction to 50 mph. Figures 13a-b-c show this phenomenon graphically. The two areas outlined in Figure 13-a are blown up in Figures 13b and 13c, and the number on each link is the ratio of the number of trips using that link if the speed limit were 50 mph. to the number of trips using the link with "normal" speed limits. A comparison of "before" and "after" trips for all zones is given in Appendix B.

CONCLUSION

STATE WIDE

CONCLUSION

In the past, it has generally been necessary to wait for the effects of a statewide policy decision such as a reduced speed limit to occur before they can be evaluated. Using a Statewide Transportation Modeling System, some of the probable impacts of a speed reduction can be examined before the actual decision is made.

Using techniques described in this report, three impacts which until now have been very difficult to evaluate can be considered: the additional driving time necessitated, the cost of that time, and the fluctuations in number of trips which are made from each region. The results presented should be taken as representative of the type of results possible with this method. Hopefully, it may serve as a basis for similar future modeling applications.

Work is now in progress on updated trip-generation-distribution equations, reflecting recent study data. It is expected that the conclusions of this report will be solidified further when the new model is operational.
