JOHN P. WOODFORD, STATE HIGHWAY DIRECTOR

June 26, 1973

Mr. Sam F. Cryderman
Engineer of Transportation Planning
Transportation Planning Division

Dear Mr. Cryderman:

The Transportation Survey and Analysis Section of the Transportation Planning Division is pleased to present a report entitled "Proximity of Automobile Injury Accidents to Hospitals".

The Proximity Analysis process is used to determine the number of injury accidents occurring within specified driving times of each of Michigan's general-purpose hospitals.

Analysis techniques such as the one described in this report begin to make true interdepartmental participation in the comprehensive statewide planning process possible. For example, executing a similar analysis on each of a number of alternative transportation plans would allow the Department of Public Health and the general public to see the probable impacts of each plan on the hospital facilities of the state; the resulting feedback would be a valuable input to the transportation planning process. Moreover, once a plan was decided upon, the proximity analysis for that plan might assist health-care planners in determining future needs.

This report was prepared by Mr. Alan Friend and Mr. Terry Gotts of the Statewide Studies Unit, Transportation Survey and Analysis Section, with the cooperation of Mr. George VanAmburg of the Michigan Department of Public Health.

Sincerely,

A handwritten signature in cursive ink that reads "Keith E. Bushnell".

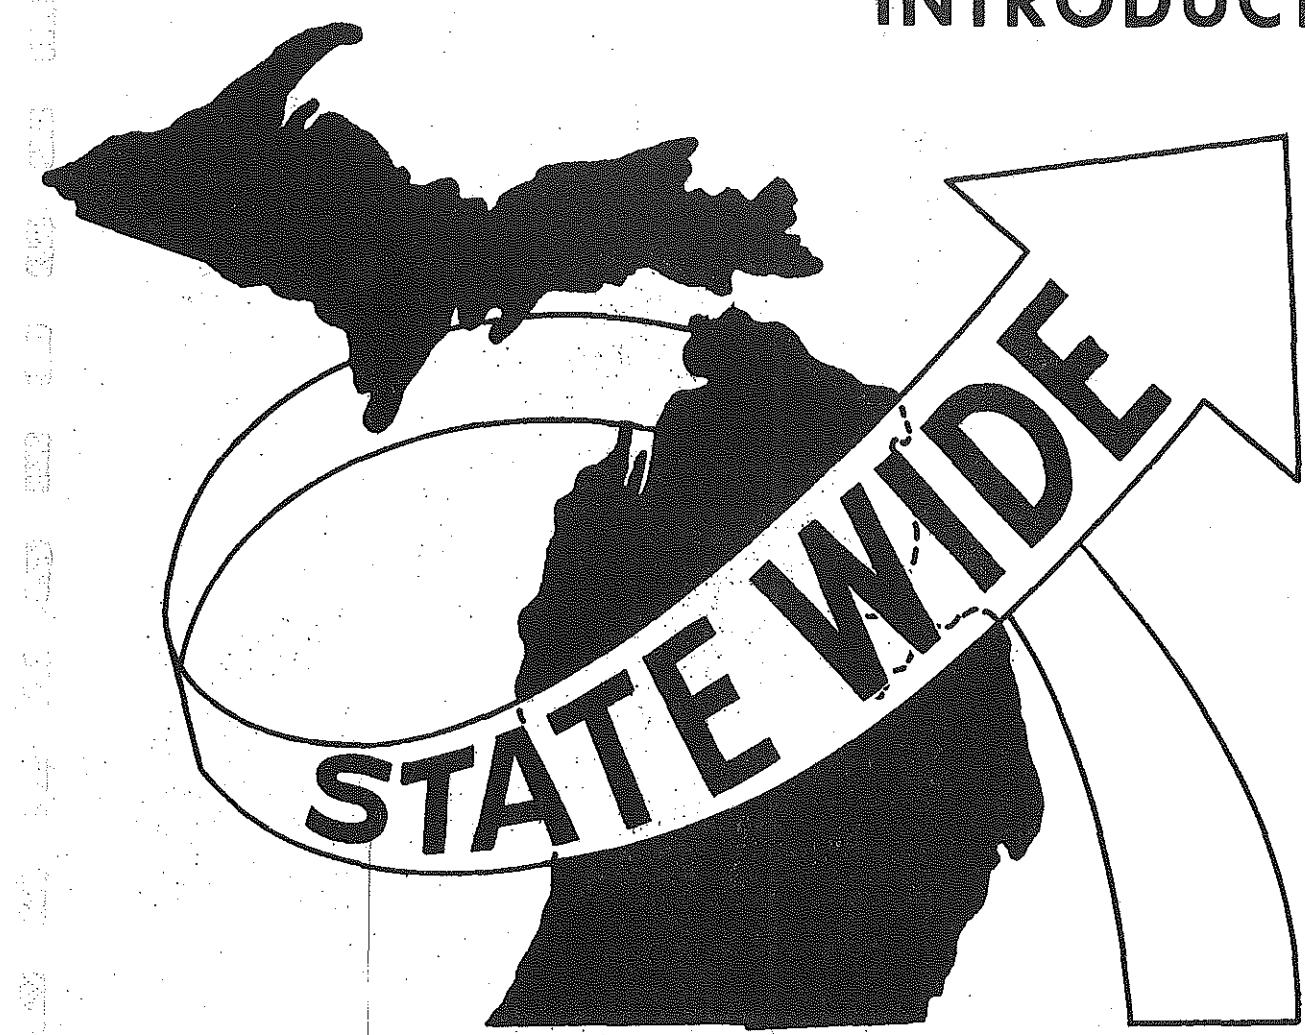

Keith E. Bushnell
Engineer of Transportation
Survey and Analysis
Section

INTRODUCTION

Introduction

After the Proximity Analysis process was deemed by the Federal Highway Administration to have "national significance" and the report given national distribution, the Statewide Studies Unit began to discover many situations in which the combination of the Statewide data-management system with Proximity Analysis could supply fast answers to practical questions. In many instances, answers which would have taken months to prepare now become available in a matter of hours.

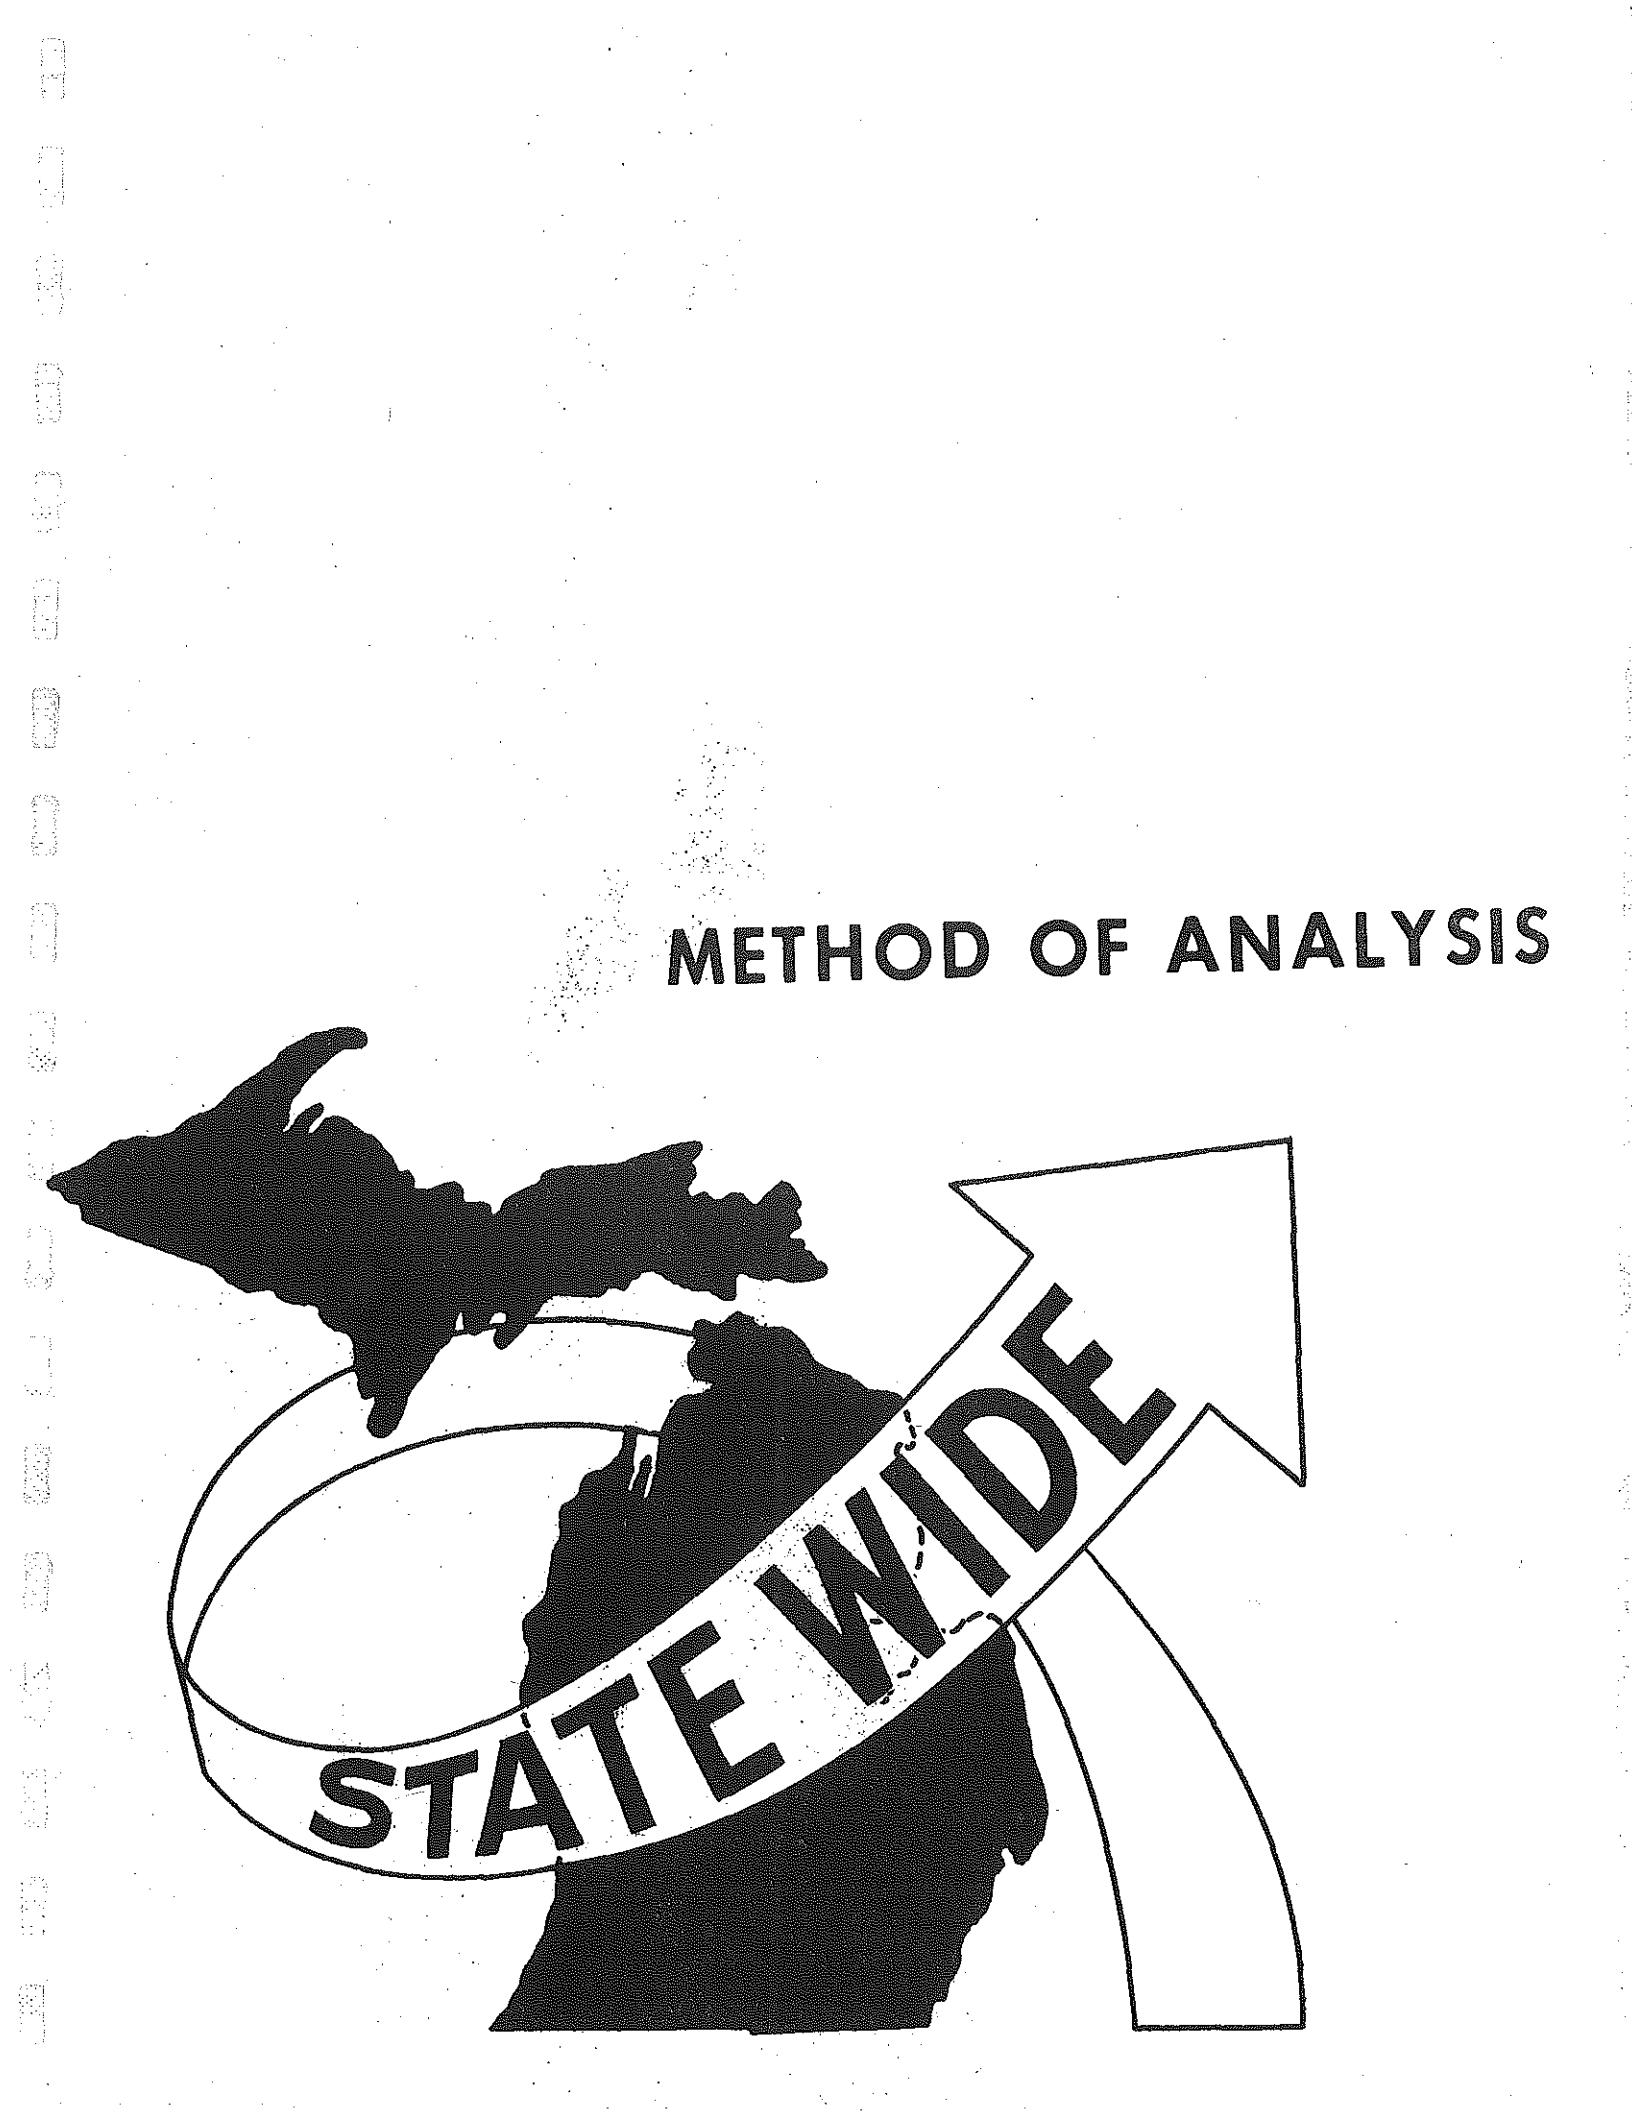

In this case, the Statewide Studies Unit was asked to supply the Michigan Department of Public Health with an analysis of the relationship of motor-vehicle injury accidents to hospitals. The questions to be answered were: What proportion of all injury accidents in Michigan occurred within 15 minutes' driving time of some hospitals? How many within 20 minutes' driving time? Are there any high-accident areas of the state which are more than twenty minutes from a hospital? How many such accidents occurred within 15 minutes or 20 minutes of a particular user-selected hospital?

The answers to such questions begin to make possible true interdepartmental cooperation in the planning process. For example, if a particular high-accident area is more than twenty minutes from the nearest hospital, three new questions are suggested at the outset: Can the highway system be changed to eliminate the source of the accidents (such as a hairpin curve or a highly-congested weaving movement)? Could a new freeway

through the area perform the double service of making hospitals more accessible and diverting traffic from a congested facility to a higher-type facility? Could a new hospital be constructed nearer to the region? Using Proximity Analysis, both transportation planners and health-care planners may quickly test each solution. This cooperation may decrease duplication of effort within state government and have the ultimate result of conserving resources of money and personnel.

This report is divided into two parts, A and B. Part A documents the analysis method and introduces each type of output. Part B contains the complete analysis and is intended to be used for detailed scrutiny.

METHOD OF ANALYSIS

STATEWIDE

Method of Analysis

Michigan's Travel Forecasting Model divides the state into 508 subareas, or "zones", as shown in Figure A1. Figure A2 provides a county cross-index for easier location of any particular zone. Trips are assumed to proceed from zone to zone on a highway "network" consisting of state trunkline and selected county roads; this network is shown graphically in Figure A3. As a spinoff of the modeling process, a special data file, called a "skimmed tree" file, is created. This file contains the average driving time from the "centroid" (center of population mass) of each zone to the centroid of every other zone, calculated along the shortest-time highway path between them.

The second principal input to the Proximity Model is the file of accident locations. Using the 1970 Accident Master File, which pinpoints the location of each accident which occurred in 1970 on Michigan's highways, one can determine the number of injury accidents which occurred on each link of the Statewide model network. It is then a short step to summarize this information to provide a file of the number of injury accidents which occurred in each Statewide zone.

Finally, it was necessary to compile the locations of Michigan's general-purpose hospitals. From a list provided by Mr. Robert Allen of the Department of Public Health, a file was created containing the number of hospitals and total number of hospital beds in each zone. Locations are not specified at

any level finer than the zone level; that is, if there are two hospitals in a zone, they are treated as one large hospital situated at the centroid of the zone. The number of hospitals in each zone is shown on the map of figure A4. This map is called a SYMAP printer-plot; darker shadings correspond to a greater number of hospitals.

Using these basic inputs, the Proximity Analysis program computes the number of accidents which occurred within driving times of 0-15 minutes and 15-20 minutes of each zone which contains at least one hospital. At the end of this section, the number of accidents occurring within 0-15 and 15-20 minutes of some (i.e., at least one) hospital is specified. Next, it considers every zone of the state and computes the number of hospitals which lie 0-15 and 15-20 minutes away. In each case, the program compares the number of injury accidents with the number of hospitals and the number of hospital beds in each time band. Finally, a list is compiled of the zones from which no hospital can be reached within twenty minutes' driving time and specifies how many accidents occurred in each zone.

FIGURE A3: NETWORK PLOT

CONSIDERATIONS AND ASSUMPTIONS

Considerations and Assumptions

Before reading the output of the Proximity Analysis, a user unfamiliar with the Statewide Modeling Process should familiarize himself with its basic assumptions. First, as has already been mentioned, all travel times are computed using a given point within each zone, called a centroid. This centroid is the approximate center of mass (population) of the zone.

Second, the time needed to traverse a given highway link is derived from the length of the link and the average driving time on the link as determined by MDSH speed studies. It cannot be emphasized too strongly that the speed on a link is not the speed limit on that link; rather, it is the effective speed for all traffic on that link.

Third, the zone-to-zone travel times do not include so-called "terminal times". Terminal time is the average additional time needed to reach one's ultimate destination once the zone centroid is reached. For example, a shopper driving to downtown Detroit must spend additional time finding a parking place and walking to a store.

Finally, the process does not subdivide zones. The accidents occurring in a zone are added to the total number within 0-20 minutes of a given hospital if, and only if, the distance between that zone and the "hospital zone" centroid is less than 20 minutes. As an example, consider a portion of the tree for zone 344, which contains Muskegon's Northshore Hospital:

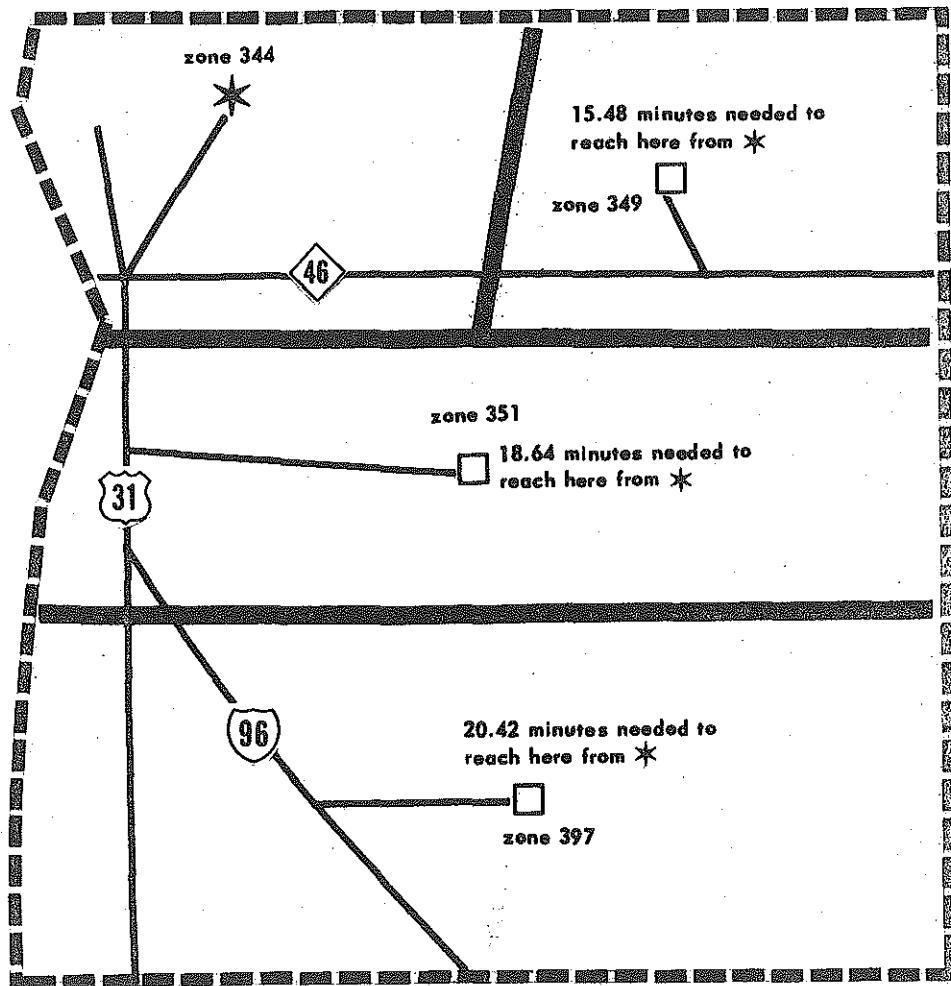

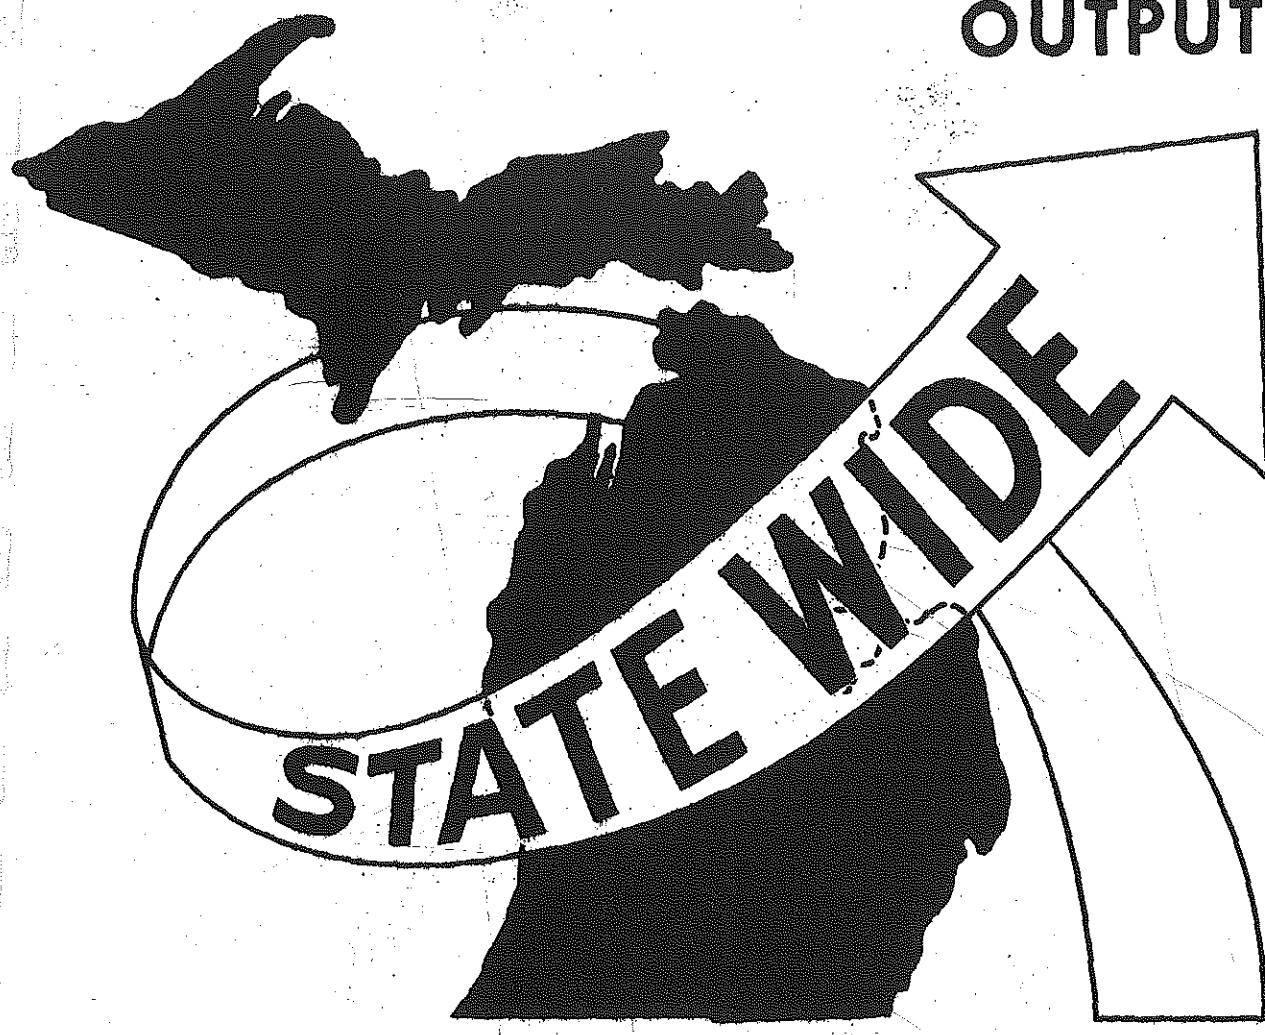

FIGURE A5: PORTION OF TREE

All of the injury accidents occurring in zones 349 and 351 would be assumed to lie within twenty minutes of zone 344. On the other hand, the accidents in zone 397 would not be considered as lying within twenty minutes of zone 344, because more than twenty minutes' driving time separates the centroids of zone 344 and zone 397. This is a simplifying assumption which has not been found to detract significantly from the results of the model.

Any problems resulting from the size of the zones in the present zone system should be alleviated by a 2300-zone system which is presently in the development stage. The zones in this system are approximately township size, which will make even finer-level proximity analyses possible.

For further information on the Proximity Analysis process,
the reader is referred to Statewide Transportation Analysis and
Research report Volume I-D entitled "Proximity Analysis: Social
Impacts of Alternate Highway Plans on Public Facilities".

EXAMPLES OF PROXIMITY ANALYSIS OUTPUT

Examples of Proximity Analysis Output

The intent of this section is to introduce the reader to the kinds of output generated in this particular proximity analysis. The analysis is reprinted in its entirety in part B of this report.

Refer now to Figure A6, which describes the concentration of injury accidents around each zone containing a hospital ("option 1 output"). The heading indicates that 146 injury accidents occurred in zone 9, and that the zone contains 1 hospital ("server") with a "capacity" of 36 beds. Within 0-15 minutes of zone 9 there occurred 146 injuries--all in suburban areas--which accounted for 0.294% of all injury accidents in Michigan. In this time band there is only 1 hospital, resulting in an "injury per server" ratio of 146.00.

Within 15-20 minutes of zone 9 there were 52 injury accidents, again occurring exclusively in suburban areas. These account for 0.105% of Michigan's injury accidents. In the "cumulative" 0-20 minute time band, there are 198 accidents (146 within 0-15 minutes, 52 within 15-20) comprising 0.398% of the total number for the state. There is only one hospital, so the injury-per-server ratio is 198.00 for the cumulative band.

Figure A7 shows the final page of the output for option 1. For Michigan as a whole, the figure shows the

15-20	5022	10.100

number of injury accidents which occurred within 0-15 and 15-20 minutes of some (that is, at least one) hospital and the proportion these are of the state total.

Figure A8 shows an example of the output for option 2, the "server proximity" option. This section considers every zone of the state in turn and calculates the concentration of hospitals ("servers") about that zone. For each driving-time band around the zone, the program calculates the number of service zones,-- that is, zones containing at least one hospital--how many hospitals are contained in these zones, and their combined capacity. In addition, the number of injury accidents occurring in the zone is divided by the number of hospitals and the total capacity (in number of beds) lying in each time band; these are expressed as an "injuries/server" ratio and an "injuries/capacity" ratio, respectively. If there are no hospitals in a particular time band, these numbers are set equal to zero by convention.

For instance, consider the two lines corresponding to zone 9. From the output from option 1, it is known that 146 accidents occurred in zone 9. Within 0-15 minutes there is one server zone containing one hospital and 36 beds; this results in an "injuries/server" ratio of $146/1 = 146.00$ and an "injuries/capacity" ratio of $146/36 = 4.06$. There are no hospitals which lie within 15-20 minutes of zone 9, so the next line contains only zeroes.

From zone 10, on the other hand, one encounters no hospitals within 0-15 minutes' driving time. One server zone lies between

10	0-15 MIN.	0	0	0.00	0.00
	15-20 MIN.	1	203	102.00	0.50

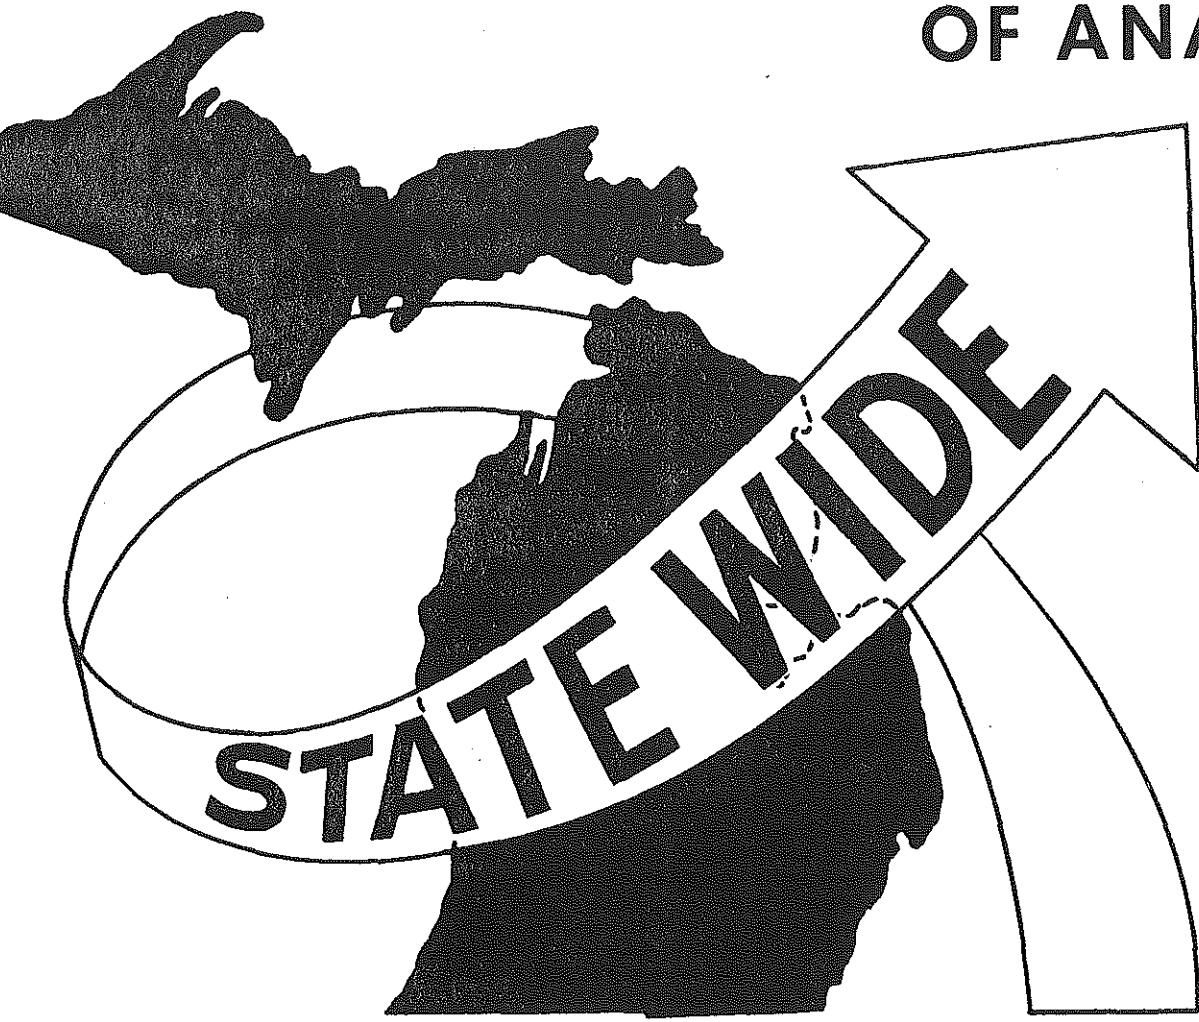

15 and 20 minutes from zone 10; it contains one hospital and 203 beds, resulting in an "injuries/server" ratio of 102.00 and an "injuries/capacity" ratio of 0.50 for the 15-20 minute driving-time band around zone 9.

The final part of option 2 (shown in figure A9) lists those zones which do not lie within twenty minutes' driving time of any hospital and the number of injury accidents occurring in each of these zones. This output is designed to help the analyst spot areas quickly in which a service deficiency is critical.

CAPSULE SUMMARY OF ANALYSIS

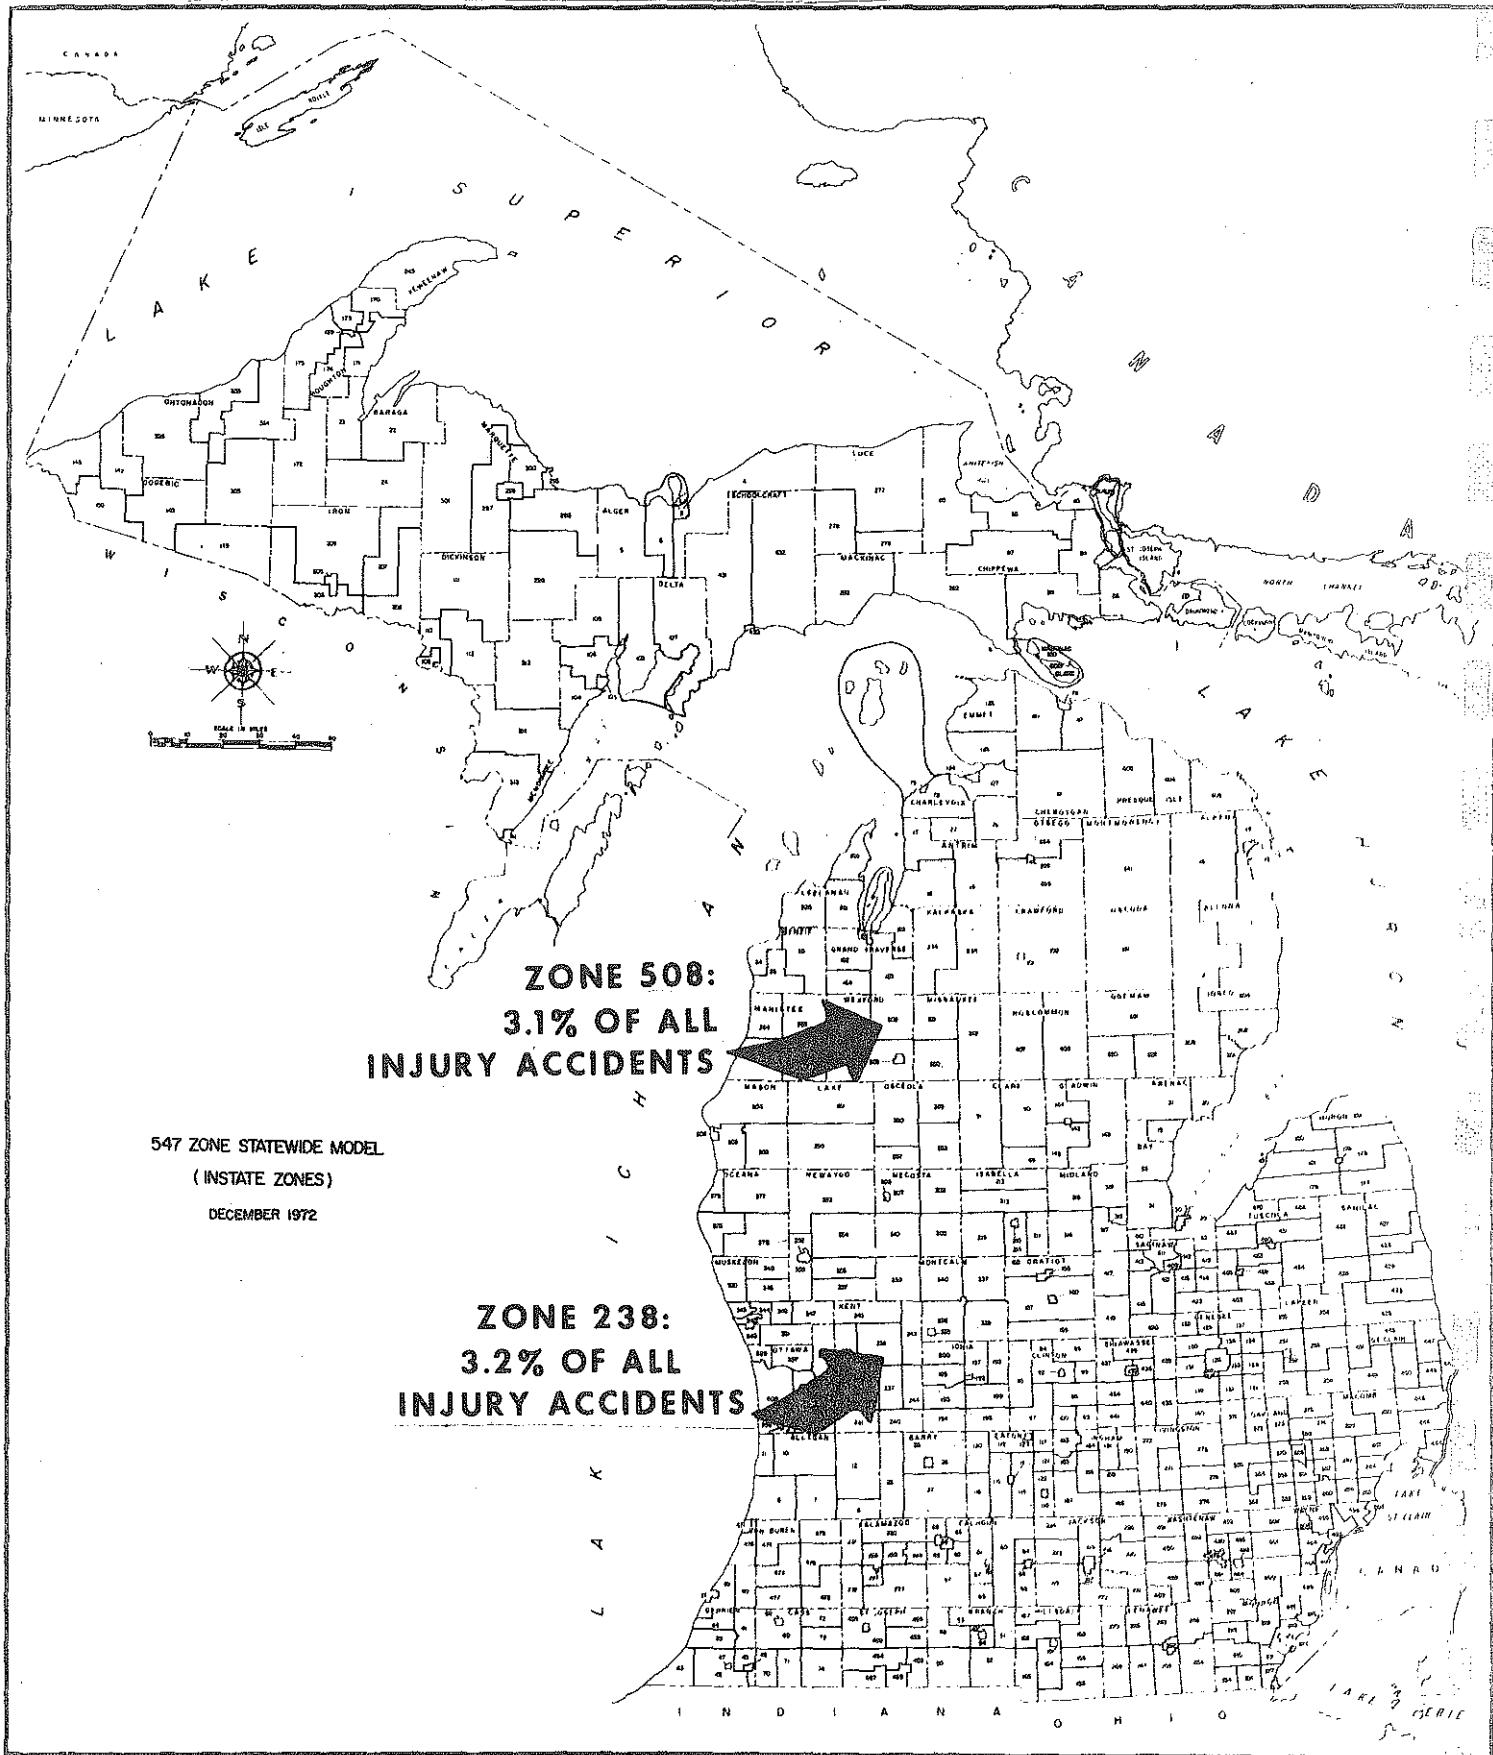

Capsule Summary of Analysis

Briefly, it is concluded (figure A7) that 37500 automobile injury accidents--75.419% of all such accidents--occurred within 15 minutes of some hospital, under the assumptions of the Proximity process. Another 5022 accidents--10.100%--occurred between 15 and 20 miles of some hospital.

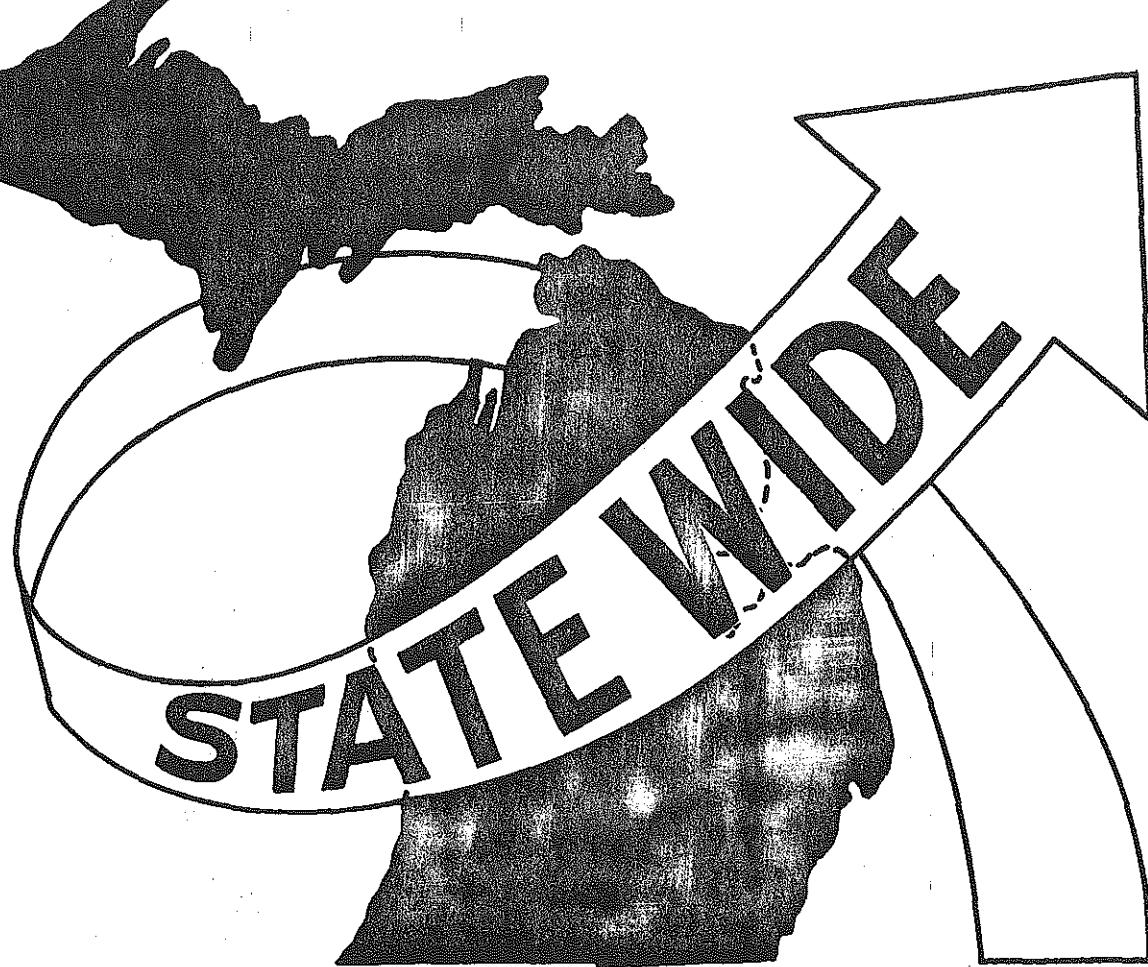

Furthermore, 7200 accidents (14.481%) occurred in zones which did not lie within 20 minutes of any hospital. Two of these zones appear more critical than the others: zone 238, northeast of Grand Rapids, and zone 508, in northeast Wexford County. Each of these areas contained slightly more than three percent of all injury. Accidents lying at least twenty minutes from every hospital. These zones are indicated on the map in figure A10.

This summary by no means contains all conclusions which can be drawn from the Proximity Analysis output. The complete analysis is printed in part B of this report.

FIGURE A10: TWO MOST CRITICAL ZONES

CONCLUSION

Conclusion

This proximity analysis is an excellent example of the way in which the quality of health care is influenced both by the physical location of hospitals and by the highway network. An improvement in the roads of a region may serve the dual purpose of making hospitals more accessible and of diverting traffic from a high-accident road to a higher-type facility with a lower accident rate. If this is not possible, the establishment of a hospital nearer the region may alleviate a part of the problem.

Studies such as this begin to open the door to true interdepartmental participation in what could possibly be a comprehensive statewide planning process. Such cooperation could have the ultimate effect of reducing duplication of effort and, consequently, of conserving resources of money and manpower.

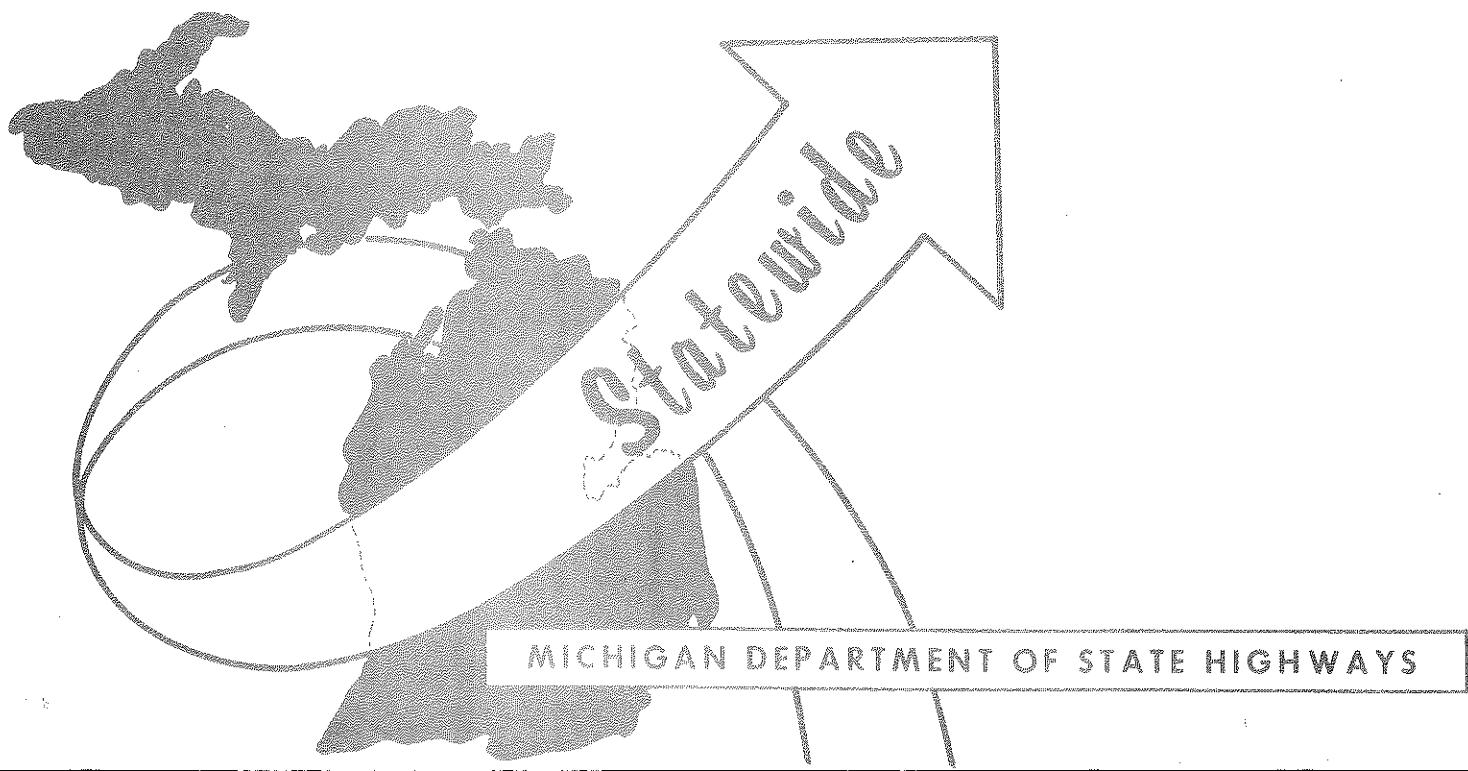

The Statewide Studies Unit welcomes recommendations for future study considerations as well as comments or suggestions concerning the Proximity Analysis process itself. Proximity Analysis appears to be a powerful planning tool; any suggestions aimed at making it still more powerful would surely be appreciated.

INTRODUCTION

Introduction

Part A of this report has discussed the method of analysis and the zone system employed. It has presented a very brief look at the output formats and the analysis results.

Part B contains the actual computer printout for the analysis of the proximity of injury accidents to hospitals. The analysis is broken down into three parts:

- (1) An analysis of the number of injuries which occur within 0-15 and 15-20 minutes of each hospital location;
- (2) The number of hospitals which lie within 0-15 and 15-20 minutes' driving time of each zone of Michigan and a comparison with the number of accidents which occur in that zone;
- (3) A list of the zones from which no hospital can be reached within 20 minutes' driving time.

This part of the report is aimed toward the analyst or planner who must do detailed analysis work. All details of the proximity analysis printout are included. Zones referred to in the printout may be located on the map of figure B1; in many cases, the analyst will find that use of the county-zone cross-index in figure B2 will greatly speed the location process.

PROXIMITY OF INJURIES TO HOSPITALS

Proximity of Injuries to Hospitals

This section of output treats each zone which contains at least one hospital. The program accumulates the number of injury traffic accidents which occur within 0-15, 15-20, and 0-20 minutes' driving time of each hospital zone.

As an example, consider the output from zone 3, which is in Alger County in the Upper Peninsula. The headings in the upper left-hand corner shows that six injury accidents occurred in zone 3, and that zone 3 has one hospital ("server") having a "capacity" of 34 beds.

Within 0-15 minutes' driving time of zone 3, there were 30 accidents, 24 in an urban area and 6 in a rural area; this comprised 0.06% of all injury accidents in Michigan. There is only one hospital in the band, giving a ratio of injuries per hospital ("server") of 30.00. The next four lines duplicate the previous data for this case.

There are no reported injury accidents within 15-20 minutes of zone 3, nor are any more hospitals encountered. Since there are no hospitals, the program sets the injuries-per-server ratio equal to zero by convention. Within 0-20 minutes, then, there are only the 30 injuries and one hospital from the 0-15 minute band, resulting in a cumulative percent of 0.060% of the state's injury accidents and an injury-per-server ratio of 30.00 for the 0-20 minute "cumulative" band.

The remainder of the section is organized in the same manner. One page of output is devoted to each hospital zone.

The last page of output in this section states that 75.419% of all injury accidents were within 0-15 minutes of at least one hospital, and another 10.100% were between 15 and 20 minutes of a hospital. Therefore, 85.519% of all injury accidents in Michigan occurred within 20 minutes of some hospital.

PROXIMITY
OF HOSPITALS
TO EACH ZONE
OF MICHIGAN

Proximity of Hospitals to Each Zone of Michigan

This section of output attempts to provide an answer to how well each zone of Michigan is being served. Each zone is examined to see how many hospitals lie within 0-15 and 15-20 minutes' driving time away, how many beds are contained in hospitals within each time band, and how this data compares with the number of accidents occurring in the zone.

The column headings deserve a word of explanation. A "service zone" is a zone which contains at least one hospital. So for a given zone and a given time band, the figure in the "service zones" column is the number of zones containing at least one hospital within that time band from the zone of origin. "Servers" means "hospitals"; thus for any given origin zone and time band, the "servers" column gives the number of hospitals in that time band. Similarly the "capacity" is the number of beds in all hospitals lying in a given time band about a zone of origin. "Injuries/server" is a ratio derived by dividing the number of injuries occurring in the origin zone by the number of hospitals lying in the time band. By the same token, "injuries/capacity" is the number of injuries in the origin zone divided by the total number of beds from all hospitals in the time band. If there are no hospitals in a given time band, these last two numbers are set equal to zero by convention.

For example, consider zone 3 again. From the last section, it is known that six injury accidents occurred in zone 3. Within 0-15 minutes, there is one service zone containing one

hospital ("server"). This hospital has 34 beds. Therefore, the "injuries/server" ratio is $6 / 1 = 6.00$, and the "injuries/capacity" ratio is $6 / 34 = 0.18$. Since there are no hospitals within 15-20 minutes, everything in the 15-20 minute row for zone 3 is set equal to zero.

As another example, look at zone 39, in which 370 injury accidents occurred. Within 0-15 minutes, there is one server zone containing two hospitals and a total of 364 beds. This gives an injury/server ratio of $370 / 2 = 185.00$ and an injury/capacity ratio of $370 / 364 = 1.02$. In the 15-20 minute band, there is one server zone which contains one hospital having 65 beds. Therefore, the injury/server ratio of $370 / 1 = 370.00$ and an injury/capacity ratio of $370 / 65 = 5.69$.

ZONES NOT SERVED

Zones Not Served

This section lists the zones from which it is not possible to reach a hospital within twenty minutes' driving time. In addition, the number of injury accidents in each of the zones is specified. Note, for example, that zone 238 has 230 accidents, but more than 20 minutes are required to reach a hospital.

The last line of this section accumulates the total number of injury accidents (7200) which occurred more than twenty minutes from a hospital. From the last page of the output for the proximity of injuries to hospitals, it is known that 42,522 injury accidents occurred within twenty minutes of some hospital, and that these are 85.519% of all injury accidents that occurred in Michigan.
