## FOREWORD

This comprehensive study was undertaken in the summer of 1964. It considers the origins and destinations of traffic on the streets and highways of the immediate Sault Ste. Marie area. Its purpose is to determine today's traffic patterns at Sault Ste. Marie as a sound basis for planning the efficient traffic arteries needed in the future. The study was initiated and conducted by the Michigan Department of State Highways with cooperation and financial assistance provided by the Bureau of Public Roads, Federal Highway Adminis. tration, U.S. Department of Transportation.

Data for the study project was derived by using sampling techniques developed by the Bureau of the Census, U.S. Department of Commerce and by the U.S. Bureau of Public Roads. The Department's Transportation Planning Division, Transportation Survey and Traffic Analysis Section tabulated the data and provided the initial analysis.

This report "Factual Data and Trip Tables," is the first of two or more reports which will present the results of the traffic study. The data in this report will serve as the basis for study and detailed recommendations by the Department's Planners and by local officials. Subsequent reports will consider the sug. gested solutions to local traffic problems, made pos: sible by this data.

## trade areas and urban centers

SAULT STE. MARIE STUDY AREA

## TERMINOLOGY AND DEFINITIONS

| Central Business (CBD): | The zones comprising the concentrated commercial and retail business center of the city. |
| :---: | :---: |
| Cordon Line: | A hypothetical line encompassing the area under study. |
| Cordon Trip: | A trip with one terminal outside the study area and one terminal inside the study area. |
| Destination: | The place where a trip ends. |
| Downtown Area: | The zones comprising the CBD and its commercial-residential fringe. |
| External: | Outside the study area. |
| External Station: | A point on a highway at the limits of the study area at which the drivers of vehicles were interviewed. |
| External Trip: | A trip with one or both of its terminals outside the study area. |
| Internal: | Within the study area. |
| Internal (Local) Trip: | A trip with both terminals inside the study area. |
| Nonresident: | A person living outside the study area. |
| Origin: | The place where the trip begins. |
| Origin-Destination Zone, O-D Zone, Zone: | A basic subdivision of the study area having a single or dominant land use, designated for purposes of tabulation and analysis. |
| Resident: | A person living within the study area. |
| Screenline: | A line through the study area on a natural or artificial division where all cross traffic is counted and classified for later comparison with the expanded surveydata. |
| Study Area: | The area enclosed by the cordon line. |
| Through Trip: | A trip passing through the study area with the terminals outside the study area. |
| Trip: | One-way travel between an origin and destination. |
| Trip Terminal: | The point where a trip begins or ends. |

## SURVEY AREA

Sault Ste. Marie is a city of 18,700 people located on the south side of the St. Mary's River, the international border between Ontario, Canada and Michigan's upper peninsula. Population within the study area is estimated at 19,000 . This area is composed of the city of Sault Ste. Marie, and the northern part of Soo Township. The total study area covers approximately 23 square miles.

## HISTORY

In 1641, Isaac Joques and Charles Raybault, Jesuit missionaries, reached the rapids at the foot of Lake Superior. They named the site the Sault de Saint Marie. Fathers Jacques Marquette and Claude Dablon, also French missionaries, arrived at the same site from Quebec in 1668 and built the first mission. The mission buildings were the first permanent structures in the state of Michigan.

In 1671, at the same location, Francois Daumont, the Sieur de St. Lusson, a nobleman and representative of King Louis XIV proclaimed that the whole interior of the continent belonged to France. This was done before an assemblage of 2000 Indians including the chiefs and warriors of 14 tribes from the North and West. The proclamation was in response to the organization of the Hudson Bay Co. chartered by the British in 1670.

Sault Ste. Marie thereafter served as a relay shipping center for hundreds of trappers who brought in their furs from as far away as the Hudson Bay area for shipment to Eastern buyers. It is said that Michigan later became known as the Wolverine State because of the trans-shipment of wolverine furs from northern Canada through the Soo.

Goods consigned to ports on the lower lakes had to be unloaded and carried to ships at the foot of the St. Marys Rapids. Upbound cargoes also had to be portaged. By the late 1840's copper discovered in the Houghton area and iron ore in the Marquette area began to demand space in down bound ships. The boats had to be dragged across the portage. A water outlet to Lake Huron became vital.

At the urging of Michigan Senators Lewis Cass and Alpheus Felch, Congress, in 1852, passed an act granting Michigan 750,000 acres of public land which could be used to finance a canal and locks. The

Michigan legislature passed an Enabling Act in Februrary of 1853 stipulating that the canal must have locks 350 feet long and 70 feet wide and be completed in two years. The project was constructed under the direction of Charles T. Harvey and employed as many as 1600 men. It was completed ahead of schedule in 1855. The canal was owned and operated by the State of Michigan from 1855 until 1881 and a toll was collected for maintenance.

Increasing traffic became too great for one set of locks and the cost of building others was too heavy a burden for Michigan to bear. Because the whole nation profited by the shipping which passed through the locks, Congress was induced to provide funds. A new lock, named after General Weitzel who was in charge of the project, was completed in 1881. It was 515 feet long and 80 feet wide. The locks were then transferred to the United States Government and all ships were given free passage.

In 1886, Congress appropriated funds to replace the state locks. The new lock was named for General Orlando Poe who supervised its construction. Completed, in 1896, the Poe Lock was 800 feet long and 80 feet wide. Canada opened it's canal the same year with a lock 900 feet long. To meet the ever growing need, a new canal and two parallel locks were constructed: The Davis Lock ready for use in 1914 and the Sabin Lock in 1919. World War II brought still heavier tonnage and in 1943 the MacArthur Lock replaced the Weitzel. The new 1968 Lock, on the site of the obsolete Poe Lock permits safe locking of vessels 1,000 feet long and 100 feet wide.

In a typical year, Great Lakes ships will make about 14,000 passages through the locks, carrying more than $80,000,000$ tons of iron ore and grain to the lower lakes. The St. Lawrence Seaway also brings a large fleet of foreign vessels to the Sault Locks heading into western Lake Superior for grain. In an average year, nearly 300 foreign vessels pass through the locks, flying the flags of 22 countries and carrying more than $4,000,000$ tons of grain to foreign nations, largely those of Western Europe. About one million tourists visit the locks each year, making them one of America's great tour ist attractions.

The International Bridge, a series of eight arch and truss spans crosses the St. Marys River and the Soo Canals. It connects Sault Ste. Marie, Michigan with Sault Ste. Marie, Ontario providing the only direct entry into Canada from the upper penninsula. The two mile long toll bridge was completed in 1962 at a

cost of $\$ 20,000,000$. The bridge is the northern terminous of Interstate Route 75 (1-75) which proceeds southerly to St. Petersburg, Florida. It is also the eastern terminous of US-2 which has its western terminous in Everett, Washington. The Soo area is also served by State Route M-129 and old US-2.

## FIELD PROCEDURE

Field work on the Sault Ste. Marie Traffic Study was conducted during the summer of 1964. The purpose was to accumulate data concerning the movement of people and goods by motor vehicle through, into, out of and within the study area.

## Internal:

Twenty percent of the dwelling units (every fifth dwelling unit) in the study area, were selected as samples on a block to block basis to insure that the sample would be consistent throughout the area.

Pertinent travel information for each occupant over five years of age of each sample dwelling unit was obtained through interviews in the home. These internal interviews were accomplished by interviewers calling in person at the sample addresses and recording the answers to the questions on Form O-D 2 (Interview Address Summary) and Form O-D 3 (Internal Trip Report).

Form O-D 2, was filled out for each sample address. Form O-D 3 was then used to record each trip made by each person, as listed under ltem " $D$ " of Form O-D 2. Any number of O-D 3 Forms may be filled out to record all trips, but only one O-D 2 is filled out for each sample address. See Appendix "B" for sample copies of each of these forms.

Information on travel by trucks and taxis was secured through interviews using a 50 percent sample of all trucks owned in the area and a 100 percent sample for taxis. The information concerning truck and taxi trips was recorded on Form O-D 7 which shows all trips performed by each vehicle for a 24 -hour day. Forms O-D 7 and O-D 8 are shown in Appendix " $B$ ". Form O-D 8 is the Coding Sheet for the trucks and taxis.

## External:

Data for the study of external trips was obtained at a cordon of interview stations established on all of the important roads leading into the study area. At each of these stations, vehicles were stopped and the drivers interviewed concerning the origin, destination and purpose of their trips.

The three state trunk line interview stations were operated for twenty-four hours with the interviewing schedule split into three eight-hour periods on three different weekdays. Two of the secondary (nontrunk

line) stations were operated with sixteen hours of interviewing with no more than 8 hours in any one weekday. One secondary station (Ferry to Sugar Island) was operated for eighteen hours, the actual time the ferry was in operation. Three local county road stations were operated for thirteen hours.

Manual vehicle classification counts were taken at all stations for twenty-four hours, except the Sugar Island Ferry where the counts were taken during the period the Ferry was in operation.

Answers to the interview questions were recorded on Form O-D 4. One line of this form was used for each vehicle interviewed. A sample copy of Form O-D 4 is shown in Appendix " B ". Both inbound and outbound vehicles were interviewed. They were recorded each hour at each station by direction of travel.

Traffic was counted and classified at twelve points on a designated screenline within the area during the survey. The screenline was established west of Seymour and Swinton Streets and along the power
canal. Vehicles were counted and classified at the Spruce Street and Portage Avenue bridges over the canal. These screenline vehicle counts were used to test the statistical characteristics of the home interviews by comparing the expanded sample to actual traffic volumes.

Traffic counts were taken by mechanical counters at 124 locations within the study area on the selected street network. One continuous count station (control station) was operated at Portage Avenue Bridge during the month of July. Turning movements were taken at three locations, 1-75 and Easterday, 1-75 and I-75 BS (3-mile road) and I-75 BS and M-129 (Ashmun). The machine and manual counts were used to compile a Traffic Flow. Map for an average weekday during July and August, 1964 as shown on page 4.

Operational fieldwork was conducted by the Traffic Survey Section of the Traffic Division. The organization of the field survey unit is shown on the following chart:

All Field work was completed, and data transmitted to Survey and Analysis Section on August 25, 1964.

## OFFICE PROCEDURE

When the field survey data was submitted to the Transportation Analysis Section, it was grouped and coded by zone and by block. To study travel habits and determine the route of travel, the Sault Ste. Marie Study Area was divided into thirty-eight analysis zones designated as "origin-destination zones". Appendix " $A$ " shows the complete breakdown of the zones by number of blocks and area in acres.

To tabulate and analyze the information obtained by the field survey, the data for each trip on the various interview forms was recorded on International Business Machine tabulation cards. The recording was done by keypunching certain combinations of numbers into the cards which represent, according to a predetermined system or code, the answers listed on the interview forms. The code numbers were entered on the interview forms by the Field Survey Section before the survey data was submitted to the Transportation Analysis Section.

Four standard punch card forms are used to record the survey data for the interview forms as follows:

| Card No. 1 | Interview Address |
| :--- | :--- |
| Summary |  |$\quad$ Form O-D 2

Reproductions of these tabulating cards are shown in Appendix " $B$ ".

After all the data has been punched into the cards and the cards verified for accuracy, the coding is edit checked. This is not a process for checking the keypunching and verifying; it is a process for checking the coding and it will detect only certain classes of errors. Two general types of errors are:
(1) Impossible codes for a single item.
(2) Impossible combination of codes between two or more items.

Specific examples to illustrate the types of errors are:

1. Impossible codes are the result of the erroneous use of code numbers to which no meaning was attached (or could be attached) when codes were set up.

Example:
A combination of zone and block numbers that does not exist.

This occurs in coding origins, destinations and other geographical locations.
2. Impossible combinations of codes for two or more items in the same card or two items each in different cards.

## Examples:

(a) In the interview Address Summary card the number of persons age 5 and up at the address must equal the sum of the number of persons age 5 and up making one trip, plus those making no trips, plus those whose number of trips is unknown.
(b) In the External Interview cards, trips with both terminals outside the area must have specific station numbers for routes of both entrance and exit. Conversely, trips with one terminal inside the area can have a specific station number only for the route of entrance or exit. The codes for direction of travel (inbound or outbound), origin, destination and route of entrance or exit are interlocked. The coding of these four items has proved highly susceptible to error. The machine checking detects these errors and they are corrected to permit logical tabulation.
(c) The residence code in the Interview Address Summary cards must be the same as the residence code in the corresponding Internal Trip Report Cards.

The machine checking is a continuous process from the start of keypunching and verifying to final machine checking.

Certain additional data, such as O-D zones and expansion factors, are also entered on the cards by gangpunching. In this manner each card is the complete record of a single trip.

A total of 24,289 cards were punched for this study.

| Punched Cards | Number Punched |
| :--- | :---: |
|  |  |
| Interview Address Summary | 1,133 |
| Internal Trip Report | 8,096 |

$\begin{array}{lr}\text { External Trip Report } & 12,534 \\ \text { Truck and Taxi Trip Report } & 2,526\end{array}$

## ADJUSTMENT OF BASIC DATA

As previously noted, the 1960 population of the Sault Ste. Marie Study Area was estimated to be 19,000 inhabitants. With a factor of 3.5 persons per dwelling unit, it was estimated that there were 5,430 dwelling units. Sampling every fifth dwelling unit would result in approximately 1,090 interview addresses. This would be $20 \%$ of the estimated 5,430 dwelling units.

There were 1,133 Interview Address Summary Cards, which indicated that the original estimate of the number of sample dwelling units was forty-three units low.

## EXPANSION AND ADJUSTMENT OF TRIP DATA

The sampling procedure resulted in a 20 percent sample as planned. If complete interviews had been obtained at each interview address it would have been possible to expand the sample to full representation by using a multiplier of five. Actually, to compensate for the incomplete interviews, it is necessary to increase the expansion factor by an increment representing the ratio of total attempted interviews to completed interviews. This factor is punched into the tabulating cards as a preliminary representation.

Previous traffic studies indicate that interviews, regarded as "complete" actually represent not the total trips performed, but only the number of trips remembered and reported to the interviewer. It is therefore necessary to examine and test the recorded data with the actual data shown by the screenline counts. From this comparison it is possible to determine the final multipliers which are required to expand the sample data to full representation. This examination consists of comparative analysis of any or all of the following phases of travel:
(1) Trips out of the area by residents: A reliable check on the amount of unreported travel by residents within the area is provided by comparing tabulations of trips to destinations outside the area reported in the internal phase of the survey with the same category of trips recorded in the external phase.
(2) Truck trips out of the area: Trips by trucks owned or garaged in the area may be tabulated and
compared in the same manner, to arrive at a measure of the unreported truck travel.
(3) Urban mass transit: Travel on the city transit system may be checked by comparing the expanded passenger trips, as reported in the survey, with the number of fares carried on an average weekday, as furnished by the transit company, if such data are obtainable.
(4) The screenline: The total passenger vehicle trips crossing the established screenline may be compared with the actual traffic volume counts at the screenline, by hour. Trucks and taxi trips across the screenline also may be compared, but usually only on the basis of twenty four-hour totals. The screenline check has proven to be most reliable as both internal and external trips are taken into account, and adjustments are made by combinations of trip purposes.

## COMPUTATION OF FINAL MULTIPLIERS

The derivation of adjustment multipliers for this study was made by comparing the actual traffic counts at the twelve screenline points with the internal interview reports of trips crossing the same screenline. It is then necessary to break down the total trips recorded as crossing the screenline by their trip purpose. This is essential in order to determine which combination of trip purposes should be adjusted to bring the interview data into agreement with the actual counts. The total trip data was first compared on an hourly basis and then for three-hour periods. Better agreement with less adjustment was found for the three-hour periods.

An examination of the "Screenline by One-Hour Periods" graph reveals that morning, noon and night work trips are more completely reported than any other. The logical conclusion is that people remember and report more completely the habitual work trips and tend to omit or forget the occasional or casual trips which also constitute a large part of their automobile travel.

Acting upon the forgoing hypothesis the interview data was segregated into various trip purposes and examined to determine in which purpose group the unreported travel had occured. For this examination, the interview data was grouped into three-hour groups and tabulated in comparison with the actual screenline count. When the difference between the actual
count and the unadjusted interview data is plotted, it results in a "deficiency curve" for the interview data. By plotting graphs of various combinations of purposes, it was determined that the purpose groups "Business, Medical-Dental, School, Social-Recreation, Change Mode of Travel, Eat Meal and Shopping" closely approximated the deficiency curve. The final adjustment applied to these groups produced reasonable agreement at the screenline.

TABLE A- 1

## Comparison of Actual Passenger Car Counts with Hourly Traffic Volumes Obtained from O-D Data

Table A-1 is for passenger car trips from both the internal and external surveys, tabulated on an hourly basis. The trips from the internal survey are subdivided into trip purposes, and the trips from the external survey subdivided into "cordon" and "through"' without regard to trip purposes. Expanded external volumes are shown with expanded and adjusted internal volumes.

Comparisons are made by hour periods because it has been found that internal trip data are reported more

SCREEN LINE COMPARISON PASSENGER CARS FINAL BY ONE-HOUR PERIODS

SCREEN LINE BY ONE-HOUR PERIODS
completely for some periods than for others. For example, many people will give complete information about their trips going to and from work but neglect to mention some of the other minor trips for other purposes. Generally, the expanded trip data will more closely approach the actual count for the morning and afternoon rush hours. Work trips predominate during these hours more than during any other periods of the day.

Because the time of crossing the screenline is not punched into the cards, it is necessary to use the "time" data obtained for other purposes. In this study, time assigned in the internal survey is the time of leaving the trip origin. This period can be used with reasonable accuracy because the distance traveled from "Origin" to the screenline is comparatively short. The time variation of only a few minutes will tend to be adjusted at the beginning and end of the hour periods. For the external survey, the time is given as the time of passing through the external interview station.

Taxis are shown at the bottom of the A-1 Table and are shown only for the total 24 -hour period. All of these trips are work trips, therefore, no further breakdown of trip purpose is shown.

A.M. HOURS P.M.

TABLE A-2
Comparison of Actual Truck Counts with Volumes Obrained from O-D Data

This table presents only the 24 -hour total. Trip purposes were not classified for these internal trips as most of the trips are known to be work trips.

## TABULATION OF DATA

The data accumulated during the course of this survey can be summarized in many different ways. It can then be applied to the study of specific problems inherent in the improvement of urban state trunk lines, the arterial street system and terminal parking facilities for motor vehicles.

Trip records are available at all times and tabulations will be prepared as the study progresses and the need is revealed. Results will be summarized and presented in appropriate form. The purpose of this report is to develop and present only certain basic tabulations. These are considered essential to demonstrate the scope of the compiled data. They are also necessary for proper use of the data in the preliminary stages of analysis.

The survey methods used resulted in the trip records containing duplications of data as follows:
(1) Trips out of the area by residents were reported on the internal interviews and recorded on the internal records. The same, or similar trips, were reported at the external stations and were recorded on the external records. To eliminate this duplication the internal records, representing trips out of the area, were sorted out and not used. This was done before any tabulations were made.
(2) Trips through the area, i.e. trips with both the origin and destination outside the area, were duplicated because such trips were recorded inbound by the interviewers at one external station and the same, or similar trips were recorded outbound by interviewers at some other external station. This duplication was eliminated by entering into the thru trips records a factor equal to one-half of the computed expansion factor. It was not necessary, therefore, to divide the tabulated figures for thru trips by two.

For the purpose of recording and analyzing the survey data, the entire study area was divided into thirtyeight zones covering four hundred and seventeen
blocks. Six coding spaces are provided on the trip record for all resident addresses, origins and destinations, places where vehicles are garaged and intermediate stops. The first three columns represent the zone and the remaining three columns represent the block. The zones and blocks are all shown on the area base map, and entered in the coding spaces are the numbers identifying the zone and blocks, within which the address is located. All tabulations of trip tables, objective trips and other geographical data, were made on the origin-destination basis. If any studies are made in which the zone area is too large, the tabulations can be made on a block basis.

It should be borne in mind that the data set forth in these tables were determined by expansion of a sample and that they are representative of week-day travel in the summer months of 1964. These data must be regarded as relative rather than absolute. They serve to establish general flow patterns which are reliable within the limits of error of the sampling procedures. Seasonal variations and anticipated future increases in traffic volumes may be estimated by applying appropriate multipliers to the basic data contained in the tables.

TABLE B- 1

## Summary of Adjusted Dwelling Unit Data

This table is compiled from data recorded in the dwelling unit summary portion of the internal interview form (Form O-D 2). All of the general statistics regarding the dwelling units, persons, and passenger cars are presented for each of the O-D zones.

## EXISTING LAND USE

## TRAFFIC VOLUME SUMMARIES

Tables of hourly traffic volumes by vehicle type were compiled from data gathered at the nine external stations. A summary of the individual station counts is shown on page 16.

In addition to the 24 -hour count, a summary of the high one-hour, two-hour and three-hour traffic volumes was compiled. It shows the percentage of each hour period at each external station to aid in the analysis of travel habits for this area. This table is reproduced on page 16.

## desire line diagrams

The following three diagrams graphically present data collected at six external interview stations: Two (2) Interstate, One (1) State Trunk Líine and Three (3) Major County Roads. They show, by means of weighted lines, the number of vehicles entering and leaving through each station. They also illustrate the interchange of vehicles with each of the other stations shown and the number of trips having terminals inside the study area. It is well to bear in mind that these are desire line diagrams only, and the traffic volumes shown are not assigned to, nor shown on, the street system.

The first diagram is designed to show distribution of through traffic. It indicates total traffic at each external station, through trips and terminal trips. On each of the succeeding two diagrams, terminal trips are further broken down to show the distribution of
trips with terminals in the principal traffic generating origin-destination zones. Past experience has demonstrated that a definite pattern of major generators will be established if data from the most significant traffic attraction zones are plotted. These zones account for approximately 50 percent of the terminal traffic from each station. The remaining 50 percent of the terminal trips will be scattered throughout the balance of the area.

Certain zones appear as the principal traffic generators on both of the diagrams illustrating terminal trips. These diagrams help guide the determination of areas to be served by State Trunk Lines. Through their use it is possible to lay out a tentative State Trunk Line system to be integrated with the major local street system. System selection and system testing by traffic assignment for Sault Ste. Marie will be presented in a subsequent report covering analysis and projections for the entire study area.

## INTERNAL DESIRE LINES

These two diagrams graphically present data collected on the Home Interview phase of the study. They show the internal trips by weighted lines interchanging between certain preselected zones of importance. Because these are desire lines only they should not by construed as reflecting a street pattern of any kind.

These preselected zones were chosen on the basis of traffic volumes, land use and importance to the community. Each diagram is labeled as to its predominant activity, e.g., central business district and commercial-residential.

Experience has proven that plotting 50 percent of a particular zone's internal traffic is sufficient to establish a pattern of generators for that zone. The remaining 50 percent will be scattered throughout the remainder of the study area. Certain zones appear as principal generators on both of the internal traffic diagrams. By studying the interrelationship of all the diagrams, the traffic patterns of the study area can be discerned. Using the internal diagrams in conjunction with the external diagrams, a tentative arterial street system can be intelligently determined.

## DISTRIBUTION OF INTERNAL TRIPS BETWEEN ZONE 11

AND OTHER ZONES BY ORDER OF IMPORTANCE

## WEEKDAY JULY-AUGUST 1964 <br> ZONE II-C.B.D.

OUT OF $\mathbf{2 0 , 7 5 1}$ INTERNAL TRIPS WITH A TERMINAL IN ZONE II, 8 ZONES ACCOUNTED FOR II,372 TRIPS (54.8\%)

## DISTRIBUTION OF INTERNAL TRIPS BETWEEN ZONE 17 AND OTHER ZONES BY ORDER OF IMPORTANCE

## WEEKDAY JULY-AUGUST 1964 ZONE 17 COMMERCIAL-RESIDENTIAL

OUT OF 6,812 INTERNAL TRIPS WITH A TERMINAL IN ZONE 17, 5 ZONES ACCOUNTED FOR 3,786 TRIPS (55.6\%)
SAULT STE. MARIE AREA TRAFFIC STUDY

## DRIVING TIME AND DISTANCE FROM CENTRAL BUSINESS DISTRICT

Average travel time for vehicles to and from the Central Business District of Sault Ste. Marie to all other parts of the survey area is graphically illustrated in Exhibit 1 on page 25. Time contours are shown in two minute intervals. The approximate center of the Central Business District has been assumed to be on Church Street between Maple and Spruce Streets.

Travel time to all points in the survey area was computed by averaging the elapsed times obtained from time runs made during the peak and off-peak hours.

This exhibit indicates that virtually all parts of the survey area are within a maximum of thirteen minutes driving time from the Central Business District. Trips to the southern part of the area have a slight time advantage due to faster speeds and shorter distances of travel.

## STATISTICS <br> OF OPERATION

## STATISTICS OF OPERATIONS

## Appendix A

For control of the survey operations and recording of data, the survey area was divided into 417 numbered blocks. These blocks were combined into 38 origindestination zones, based on the predominant land use as shown on the zone map on page XI . The land use division of the study area and the size of the resulting zones are shown in the following tabulation:

| Zone | Blocks | Acreage |
| :--- | ---: | :---: |
| 11 Central Business District | 20 | 86 |
| 12 Industrial-Public Land | 2 | 65 |
| 13 Residential | 9 | 58 |
| 14 Residential | 11 | 61 |
| 15 Residential | 10 | 56 |
| 16 Residential | 28 | 103 |
| 17 Residential-Non Manuf. | 14 | 41 |
| 18 Residential | 23 | 92 |
| 19 Residential | 14 | 112 |
| 20 Public Space | 3 | 75 |
| 21 Non Manufacturing | 8 | 229 |
| 22 Public and Vacant | 4 | 246 |
| 23 Residential | 28 | 101 |
| 24 Residential. | 32 | 124 |
| 25 Residential | 22 | 106 |
| 26 Residential-Public | 15 | 520 |
| 27 Residential-Commercial | 4 | 283 |
| 28 Public | 3 | 485 |
| 29 Residential and Rural | 28 | 1157 |
| 30 Residential | 14 | 444 |
| 31 Residential-Vacant | 11 | 281 |
| 32 Residential-Vacant | 10 | 1333 |
| 33 Rural | 4 | 1043 |
| 34 Non Manufacturing-Public | 2 | 496 |
| 35 Residential-Rural | 4 | 955 |
| 36 Residential | 9 | 475 |
| 37 Residential-Public | 33 | 463 |
| 38 Manufacturing | 8 | 63 |

| 39 | Residential | 6 | 59 |

| 40 | Manufacturing | 1 | 25 |
| 41 Residential | 4 | 53 |  |
| 42 Residential-Public | 6 | 322 |  |
| 43 Residential-Open | 7 | 670 |  |
| 44 Rural | 2 | 581 |  |
| 45 Rural | 1 | 407 |  |
| 46 | Rural | 1 | 459 |
| 47 | Residential-Rural | 4 | 362 |
| $\frac{48}{38}$ Residential | $\underline{12}$ | $\underline{62}$ |  |
| 3 | 417 | 12,553 |  |

The external cordon line around the study area connected 9 external stations where the traffic was stopped and the drivers interviewed.

Summary of operation: External

| External <br> Stations | Hours of <br> Operation | Total <br> Interviews | Percent of <br> Traffic Interviewed |
| :---: | :---: | :---: | :---: |
| 3 | 24 | 8617 | $73.9 \%$ |
| 1 | 18 | 219 | $96.5 \%$ |
| 2 | 16 | 3356 | $73.1 \%$ |
| 3 | 13 | $\underline{342}$ | $\underline{66.7 \%}$ |
| Total External |  | $\underline{12,534}$ | $\mathbf{7 3 . 8 \%}$ |

These nine external stations were operated on all main highways and important secondary roads crossing the cordon line. These stations accounted for ninety-nine percent of all trips entering and leaving the study area.

Summary of operations: Internal

| Type of Interview | No. of Units <br> Interviewed | Size of <br> Sample |
| :--- | :---: | ---: |
| Dwelling Units | 1133 | $19.2 \%$ |
| Trucks | 268 | $50.0 \%$ |
| Taxis | 18 | $100.0 \%$ |
