Lansing, January 1971

SUMMARIES OF MICHIGAN PAVEMENT ROUGHNESS 1970 Test Program

This report summarizes roughness tests conducted during the 1970 test year on new portland cement concrete, new bituminous concrete, bituminous resurfacing, and tests conducted on existing pavements after 5, 10, 15, and 20 years of service.

On the basis of riding quality, the Research Laboratory classified projects in three integrator-count categories:

"good"	(0 to 130 accumulated inches per mile)
"average"	(131 to 174 accumulated inches per mile)
"poor"	(175 or more accumulated inches per mile)

Rigid Pavement Construction (Two-Lane Pours, Conventional Construction)

Individual rigid pavement projects constructed as standard two-lane pours, and their respective roughness values as determined in the 1970 test program, are listed in Table 1. During the 20 years of roughness surveys, these integrator values have ranged from a low (smooth) of 93 to a high (rough) of 282. For 1970 the range was from 147 to 197.

Table 2 shows that since 1951, with a total of 524 rigid pavement projects tested, 36, 53, and 11 percent of this total have been rated good, average, and poor, respectively. In the 1970 test year 0, 85, and 15 percent of the 13 projects tested were rated good, average, and poor, respectively. The weighted arithmetic mean for roughness of all projects of this type tested during the 1970 test year was 167 accumulated inches per mile which represents an 8.4 percent increase in measured roughness for two-lane pours tested in 1970 over those tested in 1969.

Rigid Pavement Construction (One-Lane Pours, Conventional Construction)

Individual rigid pavement projects constructed as one-lane pours, and their respective roughness values as determined in the 1970 test program, are listed in Table 3. The testing procedure for these projects is the same as for standard two-lane pours; however, due to somewhat different construction procedures required for pours of one-lane width, the range of roughness values to be expected varies from standard two-lane pour pavements.

During the 13 years roughness tests have been conducted on this type of pavement, integrator values have ranged from a low (smooth) of 106 to a high (rough) of 276. For the 1970 test year the range was 139 to 199.

Table 4 shows that since 1958, with a total of 98 projects of this type tested, 5, 68, and 27 percent of this total have been rated good, average, and poor, respectively. In the 1970 test year 0, 71, and 29 percent of the 7 projects tested were rated good, average, and poor, respectively. The weighted arithmetic mean for roughness of all projects of this type tested during the 1970 test year was 169. This represents a 6.6 percent decrease in measured roughness of one-lane pours tested in 1970 over those tested in 1969.

Rigid Pavement Construction (Two-Lane Pours, Slip-Form Construction)

Table 5 summarizes projects tested during the 1970 test year which were constructed in two-lane pours utilizing slip-form equipment. This is the second year this method of construction has been used. Table 6 shows 7 projects of this type have been tested to date, with a weighted arithmetic mean of 181 accumulated inches per mile and ranging from 140 to 217 accumulated inches per mile.

Rigid Pavement Construction (One-Lane Pours, Slip-Form Construction)

Roughness summaries for individual projects of this type tested during the 1970 test year are given in Table 7. This was the first year for construction of this type. Roughness values ranged from 156 to 179 accumulated inches per mile with a weighted arithmetic mean of 169 accumulated inches per mile.

5, 10, 15, and 20 Year Roughness

Table 8 summarizes roughness measurements conducted on projects of past construction years during the 1970 test program. For a complete history of the projects, results of previous test programs are also included where available.

Flexible Pavement Construction (Freeway Specification)

During the 1970 test year one project was completed of this type. This project was designed to utilize the bituminous leveling course as a wearing course for approximately five years or until resurfacing is required, at which time the normal wearing course will be added. Table 9 summarizes

data for this project. Table 10 summarizes test data for all years in which this type of construction was tested.

Flexible Pavement Construction (Non-Freeway)

Results of test measurements conducted on pavements of this type during the 1970 test year are summarized in Table 11. Due to the numerous variables involved in construction of this type no attempt will be made to formulate an average roughness for these projects.

Resurfacing Projects

Results of roughness surveys on projects of this type are summarized in Table 12. Once again, due to the numerous variables in both surface type and underlying pavement, no attempt will be made to obtain an average roughness.

TABLE 1
ROUGHNESS DATA SUMMARY FOR RIGID PAVEMENT
(Two-Lane Pours, Conventional Construction)

Const. Year	Project	District	Test Length, mi.	Type	Route and Project Location	Roughness Integrator, in./mile	Paving Contractor
1968	I 06111-009	6	1.924	24' dual	I 75 comm. approx. 1400 ft SE of Maple Ridge Rd thence NWly on I 75 reloc. to Arena-Gemaw county line	147	Sargent Contracting Co. & Sargent Machinery & Equipment Co. ¹
1969	I 31051-014	1	0.655	24' dual	US 41 (reloc.) comm. at a point 280 ft W'ly of Division St thence W'ly to a point 270 ft of Pearl St, Village of Houghton	170	Proksch Construction Co.
1969	F 25084-015*	6	2.681	36' dual	M 78 from 500 ft W of Howe Rd E'ly to Vassar Rd	160	Denton Construction Co.
