JOHN P. WOODFORD, DIRECTOR

July 6, 1979

Mr. Sam F. Cryderman
Deputy Director
Bureau of Transportation Planning
Department of Transportation
P.O. Box 30050
Lansing, Michigan 48909

Dear Mr. Cryderman:

The following report was prepared in order to document the source of accident information and the standards now being used in the Statewide Transportation Modeling System to assist in the development and evaluation of regional transportation plans.

The report is oriented to use by staff of this Bureau in utilizing the capabilities of the Statewide Model. The results are not intended to replace accident data produced by the Traffic and Safety Division. Reference to the Traffic and Safety Division "Summary of Rates" is to indicate similarity in those adapted to the Statewide Model, which is a much more usable form for our purposes.

This report was prepared under the supervision of Richard E. Esch by Alan R. Friend with the assistance of W. Thomas Franklin and Charles N. Reed.

Sincerely,

A handwritten signature in cursive ink that appears to read "Edgerton W. Bailey".

Edgerton W. Bailey, Administrator
Highway Planning Division

INTRODUCTION

INTRODUCTION

The Statewide Transportation Modeling System is now being used to supply information to assist in the development and evaluation of alternate highway plans. The number of traffic accidents occurring for each alternate highway plan can be determined by using the accident rate and traffic volume associated with each road segment.

For those using the statewide model to obtain accident summaries for present or future highway plans, the following report documents the derivation of accident rates used in these calculations.

This process was completed in 1973 using 1970 data. A revised report using 1975 data follows.

ACCIDENT RATES
FOR
BASE-YEAR ROADS

ACCIDENT RATES FOR BASE-YEAR ROADS

The base-year (1975) highway network used in the transportation modeling system contains approximately 3500 road segments. Associated with each road section or link is a control-section. Accident information is stored by control-section and mileage point on the master highway accident file. By matching the two files on control-section and mileage, the number of accidents from the accident file can be accumulated for each link on the network file. This process was completed using 1975 data. Using the number of accidents, the distance, and the 1975 AADT (average annual daily traffic) the accident rate for each link was computed as follows:

$$\text{Accident Rate} = \frac{\text{Number of Accidents}}{\text{Distance} \times \text{AADT}} \times \frac{100,000,000}{365}$$

This rate represents the number of accidents per hundred million vehicle-miles.

Some control-section mismatch between the two files was created by inconsistency in the accident file or network file and by the difference in the way urban one-way streets are numbered on the two files.

About 4% of the accidents occurring on the master accident file are dropped because they occur on segments of trunkline not on the network file. These segments are usually service drives, special connectors, business routes, or trunklines which "dead-end". A list of those control-sections and mile points may be seen in Appendix A.

A few more accidents (less than 1%) are dropped because of a discrepancy in the control-section number or the length of the control-section. The number of accidents involved in each county is documented in Appendix B.

Using 1975 data, 100,775 accidents (out of 106,176) were accumulated on statewide network links. Figure 1A provides an excellent picture of the resulting accident rates throughout the state. Interstate routes which have lower accident rates than non-interstate are readily noticeable with the narrower band widths. For comparison, Figure 1B shows 1970 rates.

In addition to the number of accidents, the number of injuries and number of fatalities were transferred from the accident master file to the statewide network file. While these figures are not as stable as the number of accidents and should probably be averaged over several years, the information on injuries and fatalities may still prove worthwhile.

Figure 2 shows a table of fatal rates, injury rates, and accident rates summarized by road type. These rates were obtained by computing weighted averages of the individual link accident rates. The weighting was based on vehicle-miles. Independently, the Traffic and Safety Division has prepared a summary of rates (see Figure 3) by similar (though not exact) road categories. The fatal and injury information is not directly comparable since the Traffic and Safety summary involves fatal and injuries accident rates while those with the statewide model involve fatal and injury rates. Considering the differences,

the tables for total accident rate agree remarkably well. The largest differences occur for multi-lane divided and undivided roads. The relationship between divided and undivided has been a problem in the past. This report was originally completed in 1973 using 1970 data; and, at that time, no attempt was made to separate divided from undivided.

The reliability of the number of miles of divided versus undivided is much less than other road categories. The accident rates for undivided roadways are higher than accident rates for divided roadways, as may be expected.

FUTURE ACCIDENT RATES

STATEWIDE

FUTURE ACCIDENT RATES

Future Rates for Existing Roads

The possibility of predicting accident rates by selected physical road characteristics and by traffic-volume to capacity ratios was investigated and no significant relationship was found. For further details, see a previous statewide publication entitled: Preliminary Investigation: A Technique for the Projection of Accident Rates, April 1975, by Mark D. DuBay. This publication is available through the Statewide Procedures Section.

A comparison of Figure 1A showing 1975 accident rates and Figure 1B showing 1970 accident rates indicate that while a few sections have changed significantly most have not. The present rates will then be assumed to hold true for future years. Assuming future rates to be the same as present rates still allows the comparison of alternate transportation plans. Even though rates do not change, the actual number of accidents will change from plan to plan since the rate is expressed as the number of accidents per hundred-million vehicle miles. The vehicle-miles on each link will change according to the Statewide Model's prediction of AADT for a given year and highway plan. Until further information is available relative to the prediction of future accident rates, it is reasonable to assume that the utilization of present accident rates as future accident rates will suffice.

Future Rates For New Roads

Since proposed roads to be inserted in the Statewide Model network have no established accident rate, another approach must be used.

Most proposed roads will fall into one of three categories:

1. Rural Interstate
2. Rural Two-Lane
3. Rural Four-Lane (non-freeway)

It was felt that the summary table from Figure 2 for the present statewide network might be used as a basis for the proposed roads.

Interstate rates seem to vary little regionally; therefore, the values from Figure 2 will be used for proposed Interstate sections.

In considering new two-lane roads, Figure 2 might also be used. Since these two-lane roads include older roads having higher accident rates, newer two-lane roads were examined to see if there was any appreciable change in the accident rate. The Sufficiency Master file was compared with the statewide model network and a link was classified "newer" if:

1. Lane width was at least 12 feet
2. Year of latest improvement was 1970 or later.
3. No improvements were recommended in the next 5 years.

Using the 1975 data, "newer" roads were found to have lower rates than the "older" roads. This was also found to be true several years ago using 1970 data even though the method of determining newer roads was different.

The rates of the newer roads are summarized in Figure 4 while the rates for the remaining older roads can be seen in Figure 5.

Two-lane rural roads show a significant difference (newer = 248, older = 386).

Figure 6 shows the location of those sections falling into the newer category for rural two-lane roads. A more detailed list of these links and their characteristics as they occur on the statewide model network can be seen in Appendix C.

There were not enough links which fell into the newer category to make any conclusions about other road types except Rural Interstate which shows little difference (newer = 98, older = 102).

For remaining road types, it was felt that the summaries of existing rates (Figures 2 & 3) could serve as a guide to associating an accident rate to proposed roads. As we have seen, a newly built road would have a somewhat lower rate than the existing roads of the same type. Mainly for this reason the final rates chosen for proposed roads were biased on the low side. The final summary of rates for proposed roads can be seen in Table A. Any information to improve these figures (especially divided vs undivided) is welcomed.

Tables from the original report using 1970 data can be seen in Appendix D for comparison.
